Technical Reference

First Edition Revised (November 1983)

Changes are periodically made to the information herein; these changes will be incorporated in new editions of this publication.

Products are not stocked at the address below. Requests for copies of this product and for technical information about the system should be made to your authorized IBM Personal Computer dealer.

A Reader's Comment Form is provided at the back of this publication. If this form has been removed, address comments to IBM Corporation, Personal Computer, P.O. Box 1328-C, Boca Raton, Florida 33432. IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligations whatever.

FEDERAL COMMUNICATIONS COMMISSION RADIO FREQUENCY INTERFERENCE STATEMENT

Warning: This equipment has been certified to comply with the limits for a Class B computing device, pursuant to Subpart J of Part 15 of FCC rules. Only peripherals (computer input/output devices, terminals, printers, etc.) certified to comply with the Class B limits may be attached to this computer. Operation with non-certified peripherals is likely to result in interference to radio and TV reception.

INSTRUCTIONS TO USER

This equipment generates and uses radio frequency energy and if not installed and used properly, i.e., in strict accordance with the operating instructions, reference manuals, and the service manual, may cause interference to radio or television reception. It has been tested and found to comply with the limits for a Class B computing device pursuant to Subpart J of Part 15 of FCC Rules, which are designed to provide reasonable protection against such interference when operated in a residential installation.

If this equipment does cause interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient the receiving antenna.
- · Relocate the equipment with respect to the receiver.
- Move the equipment away from the receiver.
- Plug the equipment into a different outlet so that equipment and receiver are on different branch circuits.
- Ensure that side option mounting screws, attachment connector screws, and ground wires are tightly secured.
- If peripherals not offered by IBM are used with this equipment, it is suggested that you use shielded, grounded cables with in-line filters, if necessary.

If necessary, consult your dealer service representative for additional suggestions.

The manufacturer is not responsible for any radio or TV interference caused by unauthorized modifications to this equipment. It is the responsibility of the user to correct such interference.

CAUTION

This product is equipped with a UL listed and CSA-certified plug for the user's safety. It is to be used in conjunction with a properly grounded 115 Vac receptacle to avoid electrical shock.

Preface

The IBM PCjr Technical Reference manual describes the hardware design and provides interface information for the IBM PCjr. This publication also has information about the basic input/output system (BIOS) and programming support.

The information in this publication is both descriptive and reference oriented, and is intended for hardware and software designers, programmers, engineers, and interested persons who need to understand the design and operation of the IBM PCjr computer.

You should be familiar with the use of the IBM PCjr, and understand the concepts of computer architecture and programming.

This manual has five sections:

Section 1: "Introduction" is an overview of the basic system and available options.

Section 2: "Base System" describes each functional part of the base system. This section also has specifications for power, timing, and interfaces. Programming considerations are supported by coding tables, command codes, and registers.

Section 3: "System Options" describes each available option using the same format as Section 2: "Base System."

Section 4: "Compatibility with the IBM Personal Computer Family" describes programming concerns for maintaining compatibility between the IBM PCjr and the other IBM Personal Computers.

Section 5: "System BIOS and Usage" describes the basic input/output system (BIOS) and its use. This section also contains the software interrupt listing, a system memory map, descriptions of vectors with special meanings, and a set of low-storage maps. In addition, keyboard encoding and usage is discussed.

This publication has four appendixes:

Appendix A: "ROM BIOS Listing" Appendix B: "Logic Diagrams"

Appendix C: "Characters, Keystrokes, and Color"

Appendix D: "Unit Specifications"

Prerequisite Publication:

Guide to Operations part number 1502291

Guide to Operations part number 1502292

SECTION 1. INTRODUCTION

Conten	112	

Introduction	l·	-

Introduction

The system unit, a desk top transformer, and a cordless keyboard make up the hardware for the PCjr base system.

The following options are available for the base system:

- IBM PCjr 64KB Memory and Display Expansion
 - The 64KB Memory and Display Expansion enables the user to work with the higher density video modes while increasing the system's memory size by 64K Bytes to a total of 128K Bytes.
- IBM PCjr Diskette Drive Adapter
 - The IBM PCjr Diskette Drive Adapter permits the attachment of the IBM PCjr Diskette Drive to the IBM PCjr and resides in a dedicated connector on the IBM PCjr system board.
- IBM PCjr Diskette Drive
 - The IBM PCjr Diskette Drive is double-sided with 40 tracks for each side, is fully self-contained, and consists of a spindle drive system, a read positioning system, and a read/write/erase system.
- IBM PCjr Internal Modem
 - The IBM PCjr Internal Modem is an adapter that plugs into the PCjr system board modem connector and allows communications over standard telephone lines.

IBM PCjr Parallel Printer Attachment

 The IBM PCjr Parallel Printer Attachment is provided to attach various I/O devices that accept eight bits of parallel data at standard TTL logic levels. It attaches as a feature to the right side of the system unit.

• IBM Personal Computer Graphics Printer

 IBM Graphics Printer is an 80 cps (characters-per-second), self-powered, stand-alone, tabletop unit.

• IBM PCjr Joystick

 The IBM PCjr Joystick is an input device to provide the user with two-dimensional positioning-control. Two pushbutton switches on the joystick give the user additional input capability.

IBM Color Display

 The IBM Color Display is a Red/Green/Blue /Intensity (RGBI) Direct-Drive display, that is independently housed and powered.

IBM Connector for Television

 The IBM Connector for Television allows a TV to be connected to the IBM PCjr system.

IBM PCjr Keyboard Cord

 The IBM PCjr Keyboard Cord option is used to connect the IBM PCjr Cordless Keyboard to the system board.

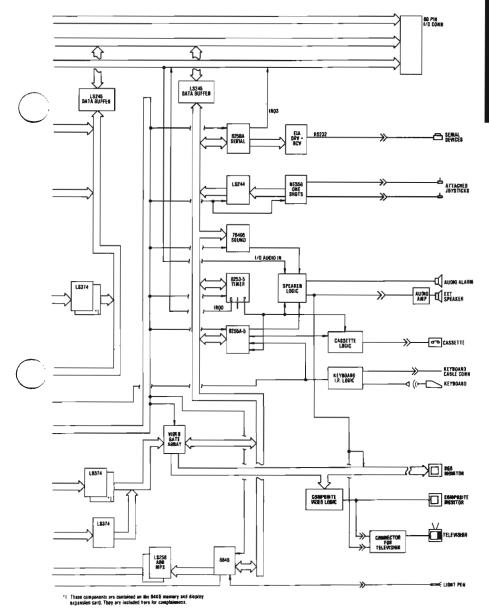

- IBM PCjr Adapter Cable for Serial Devices
 - This option is an adapter cable that allows connection of serial devices to the IBM PCjr system board.
- IBM PCjr Adapter Cable for Cassette
 - This option is an adapter cable that allows a cassette recorder to be connected to the IBM PCjr.
- IBM PCjr Adapter Cable for Color Display
 - This adapter cable allows the IBM Color Display to be connected to the IBM PCjr.

The following is a block diagram of the IBM PCjr system.

Introduction

The PCjr base-system hardware consists of the system unit, a 62-key cordless-keyboard, and a power transformer.

The PCjr system board is the center of the PCjr system unit. The system board fits horizontally in the base of the system unit and is approximately 255 mm by 350 mm (10 inches by 13.8 inches). It is double-sided, with an internal-power/ground plane. Low voltage ac power enters the power supply adapter, is converted to dc voltage, and enters the system board through the power supply adapter edge-connector. Other system board connectors provide interfaces for a variety of input/output (I/O) devices and are individually keyed to prevent improper installation. The following is a list of these connectors:

- 64KB Memory and Display Expansion Connector
- Diskette Drive Adapter Connector
- Internal Modem Connector
- Infra-Red (IR) Link Receiver Board Connector
- Program Cartridge Connectors (2)
- I/O Channel Expansion Connector
- Serial Port (RS232) Connector (with optional adapter cable)
- Direct Drive (RGBI) Video Connector
- Composite Video Connector
- IBM Connector for Television Connector (external RF modulator)
- Light Pen Connector
- External Audio Connector
- IBM PCjr Keyboard Cord Connector
- Cassette Connector (with optional adapter cable)
- IBM PCjr Attachable Joystick Connectors (2)

The system board consists of seven functional subsystems: the processor subsystem and its support elements, the read-only (ROM) subsystem, the read/write (R/W) subsystem, the audio subsystem, the video subsystem, the games subsystem, and the I/O channel. All are described in this section.

The nucleus of the system board is the Intel 8088 microprocessor. This processor is an 8-bit external bus version of Intel's 16-bit 8086 processor, and is software-compatible with the 8086. The 8088 supports 16-bit operations, including multiplication and division, and supports 20 bits of addressing (1 megabyte of storage). It operates in the minimum mode at 4.77 MHz. This frequency, which is derived from a 14.31818-MHz crystal, is divided by 3 for the processor clock, and by 4 to obtain the 3.58-MHz color-burst signal required for color televisions.

For additional information about the 8088, refer to the publications listed in "Bibliography".

The processor is supported by a set of high-function support-devices providing three 16-bit timer-counter channels, and nine prioritized-interrupt levels.

The three programmable timer/counters are provided by an Intel 8253-5 programmable interval-timer and are used by the system in the following manner: Channel 0 is used as a general-purpose timer providing a constant time-base for implementing a time-of-day clock; Channel 1 is used to deserialize the keyboard data and for time-of-day overflow during diskette operations. Channel 2 is used to support the tone generation for the audio speaker and to write data to the cassette.

Of the nine prioritized levels of interrupt, three are bused to the system's I/O channel for use by adapters. Five levels are used on the system board. Level 0, the

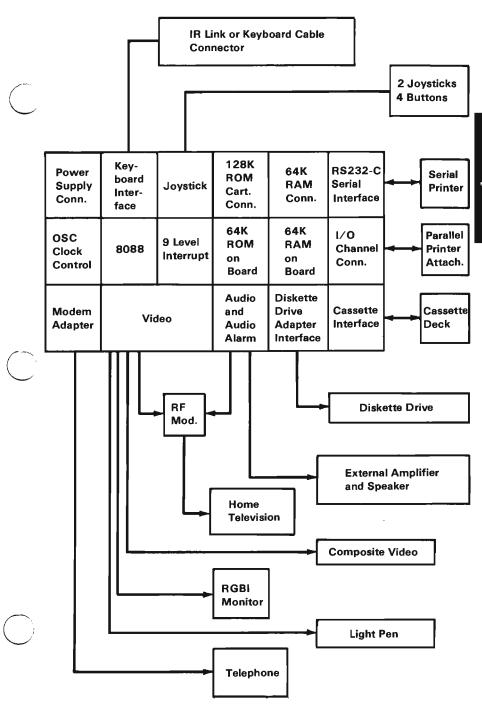

highest priority, is attached to Channel 0 of the timer/counter and provides a periodic interrupt for the time-of-day clock; level 3 is the serial-port-access interrupt; level 4 is the modem-access interrupt; level 5 is the vertical-retrace interrupt for the video; and level six is the diskette drive adapter-access interrupt. The non-maskable interrupt (NMI) of the 8088 is attached to the keyboard-interface circuits and receives an interrupt for each scan code sent by the keyboard.

The system board supports both read-only memory (ROM) and R/W memory (RAM). It has space for 64K bytes by 8 bits of ROM. There are two module sockets that accept a 32K byte by 8 bit ROM module. ROM is aligned at the top of the 8088's address space. This ROM contains the Power-On Self-Test, cassette-BASIC interpreter, cassette-operating system, I/O drivers, dot patterns for 256 characters in graphics mode, a diskette bootstrap-loader and user-selectable diagnostic-routines.

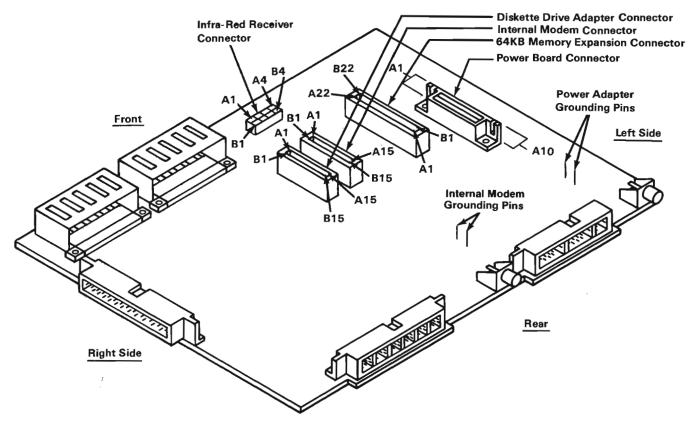

The system board contains the following major functional components:

- 8088 Microprocessor
- 64K ROM
- 128K ROM Cartridge Interface
- 64K Dynamic RAM
- 64KB Memory and Display Expansion Interface
- Serial Port (RS232)
- Audio Alarm (Beeper)
- Sound Subsystem
- Cassette Interface
- Joystick Interface
- · Keyboard Interface
- · Modem Interface
- · Diskette Interface
- Video/Graphics Subsystem
- · Light Pen Interface
- I/O Expansion Bus
- 9-Level Interrupt

The following is a block diagram of the System Board.

System Board Connector Specifications (Part 3 of 3)

Processor and Support

The (R) Intel 8088 Microprocessor is used as the system's central processor. Some of its characteristics are:

- 4.77 MHz clock
- 20 bit address bus
- 8-bit memory interface
- 16-bit ALU (arithmatic/logic unit) and registers
- Extensive instruction set
- DMA and interrupt capabilities
- · Hardware fixed-point multiply and divide

The system clock is provided by one Intel 8284A clock chip. The 8088 is operated in the minimum mode.

Performance

The 8088 is operated at 4.77 MHz which results in a clock cycle-time of 210 ns.

Normally four clock cycles are required for a bus cycle so that an 840 ns ROM memory cycle time is achieved. RAM write and read cycles will incur an average of two wait states because of sharing with video, leading to an average of six clock cycles. I/O reads and writes also take six clock cycles leading to a bus cycle time of $1.260~\mu s$.

Notes:

8259A Interrupt Controller

PCjr Hardware Interrupts

Nine hardware levels of interrupts are available for the PCjr system. The highest-priority interrupt is the NMI interrupt in the 8088. The NMI is followed by eight prioritized interrupt-levels (0-7) in the 8259A Programmable Interrupt Controller, with IRQ 0 as the highest and IRQ 7 as the lowest. The interrupt level assignments follow:

Level		Function
8088	NMI	Keyboard Interrupt
8259A 8259A 8259A 8259A 8259A 8259A 8259A	IRQ 0 IRQ 1 IRQ 2 IRQ 3 IRQ 4 IRQ 5 IRQ 6 IRQ 7	Timer Clock Interrupt I/O Channel (Reserved) I/O Channel Asynchronous Port Interrupt (RS-232C) Modem Interrupt Vertical Retrace Interrupt (Display) Diskette Interrupt I/O Channel (Parallel Printer)

Hardware Interrupts

8259A Programming Considerations

The 8259A is set up with the following characteristics:

- Buffered Mode
- 8086 Mode
- Edge Triggered Mode
- Single Mode Master (No Cascading is Allowed)

The 8259A I/O is located at I/O address hex 20 and hex 21. The 8259A is set up to issue interrupt types hex 8 to hex F which use pointers to point to memory address hex 20 to hex 3F.

The following figure is an example setup.

0263 BO 13	MOV	AL, 13H	; ICW1 - Reset edge sense circuit set single ; 8259 Chip and ICW4 read
0265 E6 20	OUT	INTA00,AL	
0267 BO 08	MOV	AL,8	; ICW2 - Set interrupt type 8 (8-F)
0269 E6 21	OUT	INTA01,AL	
026B BO 09	MOV	AL,9	; ICW4 - Set buffered mode/master and 8086 mode
026D E6 21	OUT	INTA01,AL	

Example Set Up

64K RAM

The 64K bytes of R/W memory reside on the system board and require no user configuration.

Eight 64K byte by 1, 150 ns, dynamic memory modules are used to provide 64K byte of storage. The RAM has no parity. Sources of these memory modules include the Motorola MCM6665AL15 and the Texas Instruments TMS4164-15 or equivalent.

The system board 64K RAM is mapped at the bottom of the 1 MEG address space. The system board 64K RAM is mapped to the next 64K bytes of address space if the 64KB Memory and Display Expansion option is not installed. If read or written to, this higher block of address space will look just like the low-order 64K-byte block. This means the bottom 128K bytes of address space is always reserved for RAM. If the 64KB Memory and Display Expansion option is installed, it is mapped to the 'ODD' memory space within the 128K byte-reserved space while the system board memory is mapped to the 'EVEN' space. Memory refresh is provided by the 6845 CRT Controller and gate array. The gate array cycles the RAM and resolves contention between the CRT and processor cycles.

See "IBM PCjr 64KB Memory and Display Expansion" in Section 3 for a detailed description.

Notes:

ROM Subsystem

The ROM subsystem is made up of 64K bytes of ROM aligned at the top of the 1 MEG address space. The ROM is built using 32K byte by 8 ROM-modules. The ROM has no parity. The general memory specifications for the ROM are:

Access Time - 250 ns Cycle Time - 375 ns

ROM modules Mk 38000 from Mostek, TMM23256P or equivelent are used. Address A14 is wired to both pin 1 and pin 27.

The following figure is a map of the sections of memory allocated for use by the system:

	FFFFF)

Expansion RAM	10000	
Base RAM		
	00000	

Memory Map

Input Output Channel

The Input/Out channel (I/O) is an extension of the 8088 microprocessor bus. It is however, demultiplexed, repowered, and enhanced by the addition of interrupts.

The I/O channel contains an 8-bit bidirectional bus, 20 address lines, 3 levels of interrupt, control lines for memory and I/O read or write, clock and timing lines, and power and ground for the adapters. Voltages of +5 dc and +12 dc are provided for external adapters. Any additional power needs will require a separate power-module.

All I/O Channel functions are bused to the right-hand side of the system unit and are provided by a right-angle, 60-pin connector. Each external adapter connects to the I/O bus and passes the bus along for the next attachment.

A 'ready' line is available on the I/O Channel to allow operation with slow I/O or memory devices. If the channel's 'ready' line is not activated by an addressed device, all processor-generated memory-read and write cycles take four 210-ns clocks or 840-ns/byte. All processor-generated I/O-read or write cycles require six clocks for a cycle time of $1.26-\mu s/byte$.

The I/O Channel also contains the capability to add bus masters to the channel. These devices could be DMA devices or alternate processors.

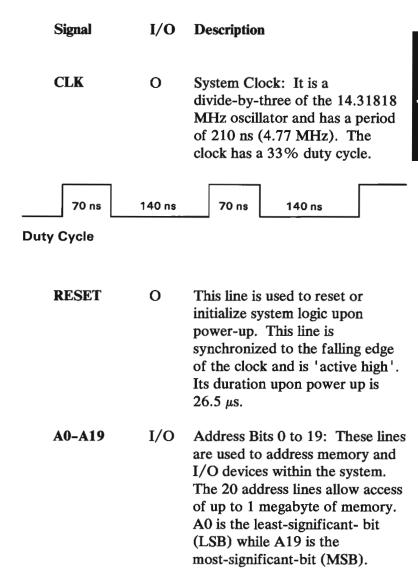

The I/O Channel signals have sufficient drive to support five I/O Channel expansion-adapters and the internal modem and diskette drive adapter, assuming one standard TTL load per attachment. For information on power available for external adapters, see "System Power Supply", later in this Section.

I/O Channel Expansion Connector Specifications

System Board I/O Channel Description

The following is a description of the I/O Channel. All signals are TTL compatible.

These lines are normally driven by the 8088 microprocessor as

outputs, but can become inputs from an external bus-master by issuing an HRQ and receiving an HLDA.

D0-D7

I/O Data Bits 0-7: These lines provide data-bus bits 0 to 7 for the processor, memory, and I/O devices. D0 is the least-significant-bit (LSB) and D7 is the most-significant-bit (MSB). These lines can be controlled by an external bus-master by issuing an HRQ and receiving an HLDA.

ALE

O Address Latch Enable: This line is provided to allow the addition of wait states in memory and I/O cycles.

READY

I This line, normally 'high' ('ready'), is pulled 'low' ('not ready') by a memory or I/O device to lengthen I/O or memory cycles. It allows slower devices to attach to the I/O Channel with a minimum of difficulty. Any slow device requiring this line should drive it 'low' immediately upon detecting a valid address and IO/-M signal. Machine cycles (I/O and memory) are extended by an integral number of CLK cycles (210 ns). Any bus master on the I/O Channel should also honor this 'ready' line. It is pulled 'low' by the system board

on memory read and write cycles and outputting to the sound subsystem.

IRQ1, IRQ2, IRQ7

I Interrupt Request 1, 2, and 7:
These lines are used to signal the processor that an I/O device requires attention. They are prioritized with IRQ1 as the highest priority and IRQ7 as the lowest. An Interrupt Request is generated by raising an IRQ line ('low' to 'high') and holding it 'high' until it is acknowledged by the processor (interrupt-service routine).

-IOR

I/O I/O Read Command: This command line instructs an I/O device to drive its data onto the data bus. This signal may be driven by the 8088 microprocessor or by an external bus-master after it has gained control of the bus. This line is active 'low'.

-IOW

I/O I/O Write Command: This command line instructs an I/O device to read the data on the data bus. This signal may be driven by the 8088 microprocessor or by an external bus-master after it has gained control of the bus. This line is active 'low'.

-MEMR

I/O Memory Read Command: This command line instructs the

memory to drive its data onto the data bus. This signal may be driven by the 8088 microprocessor or by an external bus-master after it has gained control of the bus. This line is active 'low'.

-MEMW

I/O Memory Write Command: This command line instructs the memory to store the data present on the data bus. This signal may be driven by the 8088 microprocessor or by an external bus-master after it has gained control of the bus. This line is active low

IO/-M

I/O or Memory Status: This status line is used to distinguish a memory access from an I/O access. This line should be driven by a bus master after it has gained control of the bus. If this line is 'high' it indicates an I/O Address is on the Address Bus; if this line is 'low', it indicates a memory address is on the Address Bus.

-HRQ

I Hold Request: This line indicates that another bus master is requesting the I/O Channel. To gain bus-master status, a device on the channel must assert -HRQ (active 'low'). The 8088 will respond to a -HRQ by asserting an HLDA. After receiving an HLDA, the new bus master may

control the bus, and must continue to assert the -HRO until it is ready to relinquish the bus. A -HRQ is not an asynchronous signal and should be synchronized to the system clock. All channel devices with bus-master capabilities must latch data-bit D4 during any 'Out' instruction to A0-A7. The resulting signal should be used to qualify -HRQ as follows: Latched value = 1 --> -HRQ is inhibited. Latched value = 0 -->-HRO is allowed. For more detail, see the explanation of the A0 port.

- DRQ 0

 This line comes from the floppy disk controller (FDC) and can be used by an external DMA to indicate that a byte should be transferred to the FDC.
- -DACK 0 I This line should come from an external DMA and should indicate that a byte is being transferred from memory to the FDC.
- HLDA O Hold Acknowledge: This line indicates to a bus master on the channel that -HRQ has been honored and that the 8088 has floated its bus and control lines.

-CARD SLCTD

Ι

I

This line should be pulled down by any adapter when it is selected with address and IO/-M. This line will be used for bus expansion. It is pulled up with a resistor and should be pulled down with an open collector device.

AUDIO IN

Channel devices may provide sound sources to the system-board sound-subsystem through this line. It is 1 volt peak-to-peak, dc biased at 2.5 volts above ground.

8255 Bit Assignment Description

PA0 thru (Output PA7 Lines)

Port A is configured as an output. The output lines are not used by the hardware, but are used to store keystrokes. This is done to maintain compatibility with the Personal Computer, and Personal Computer XT.

PB0 (+Timer 2 Gate)

This line is routed to the gate input of timer 2 on the 8253-5. When this bit is 'low', the counter operation is halted. This bit and PB1 (+Speaker Data) controls the operation of the 8253-5 sound source.

PB1 (+Speaker Data)

This bit ANDS 'off' the output of the 8253-5 timer 2. It can be used to disable the 8253-5 sound source, or modify its output. When this bit is a 1, it enables the output, a 0 forces the output to zero.

PB2 (+Alpha -Graphics) This bit is used to steer data from the memory into the Video Gate Array. This bit should be a 1 for all alpha modes, and a 0 for all graphics modes.

PB3 (+Cassette W Motor Off) re

When this bit is a 1, the cassette relay is 'open' and the cassette motor is 'off'. When this bit is a 0, and PB4 = 0, the cassette motor is 'on'.

PB4 (+Disable internal beeper and cassette motor relay)

When this bit is a 1, the internal beeper is 'disabled' and the 8253-5 timer 2 sound source can only be heard if it is steered to the audio output. This bit also disables the cassette motor when it is a 1. To 'enable' the cassette motor, this bit must be a 0. In this case, PB1 should be used to gate 'off' the internal beeper and 8253-5 sound source.

PB5, (Speaker PB6 switch 0,1)

These bits steer one of 4 sound sources. This is available to the RF modulator or the external audio jack. The sound sources selected are shown below.

PB6	PB5	Sound Source
0	0	8253-5 Timer 2
0	1	Cassette Audio Input
1	0	I/O Channel Audio In
1	1	76496

PB7 (Open)

Reserved for future use.

PC0 (Keyboard latched)

This input comes from a latch which is set to a 1 on the first rising edge of the Keyboard Data stream. The output of this latch also causes the NMI to occur. This latch is cleared by doing a dummy 'Read' operation to port A0. This input is provided so that a program can tell if a keystroke occurred during a time when the NMI was masked 'off' and a keystroke has been missed. The program will then be able to give an error indication of the missed keystroke.

PC1 (-Modem card installed)

When this bit is a 0, it indicates that the Internal Modem card is installed.

PC2 (-Diskette card installed)

When this bit is a zero, it indicates that the Diskette Drive Adapter is installed.

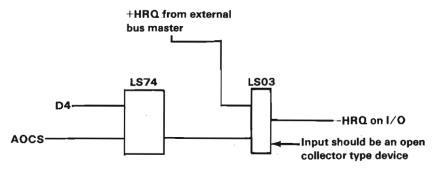

PC3 (-64KB Memory and Display Expansion installed) When this bit is a 0, it indicates that the 64KB Memory and Display Expansion is installed.

PC4	(Cassette data in)	If the cassette-motor relay is 'closed', and the cassette motor is 'on', this pin will contain data which has been wave shaped from the cassette. If the cassette-motor relay is 'off', this pin will contain the same data as the 8253-5 timer 2 output.
PC5	(Timer channel 2 output)	This input is wired to the timer channel 2 output of the 8253-5.
PC6	(+Keyboard data)	This input contains keyboard data. The keyboard data comes from the cable if attached, or from the IR Receiver if the cable is not attached.
PC7	(-Keyboard cable	If this bit is 'low', it indicates that the keyboard cable is connected.

connected)

Port A0 Output Description

	•	•
D7	(Enable NMI)	When this bit is a 1, the NMI is 'enabled'. When it is a 0, it is 'disabled'.
D6	(IR test ENA)	This bit enables the 8253-5 timer 2 output into an IR diode on the IR Receiver board. This information is then wrapped back to the keyboard input. If the cable is not connected, timer 2 should be set for 40 kHz which is the IR-modulation frequency. This feature is used only for a diagnostic test of the IR Receiver board.
D5	(Selc Clk1 input)	This bit selects one of two input Clks to the 8253-5 timer 1. A 0 selects a 1.1925 MHz Clk input used to assist the program in de-serializing the keyboard data. A 1 selects the timer 0 output to be used as the Clk input to timer 1. This is used to catch timer 0 overflows during diskette drive operations when interrupts are masked 'off'. This is then used to update the time-of-day.
D4	(+Disable HRQ)	This bit is not actually implemented on the system board, but is supported by the programming. This bit is used to disable -HRQs from external bus-masters (DMA, Alternate Processors, etc.) The logic for this bit must exist on each bus-master attachment. A 0 should 'enable' -HRQ, and a 1 should 'disable' -HRQ.

Port A0 Output Description

Port A0 Input Operation

A 'read' to I/O port A0 will clear the keyboard NMI latch. This latch causes an NMI on the first rising edge of the keyboard data if the enable NMI bit (port A0 bit D7) is 'on'. This latch can also be read on the 8255 PC0. The program can determine if a keystroke occurred while the NMI was 'disabled' by reading the status of this latch. This latch must be cleared before another NMI can be received.

The System board provides for selection of keyboard data from either a cable or the IR-receiver board. The IR-receiver board is mounted on the system board and can receive data through an IR link. The source of the keyboard's data is determined by the -Cable Connected signal at the keyboard cable connector. Keyboard serial data is available to the 8088 at bit PC6 of the 8255 PPI.

The system board is responsible for the de-serialization of keyboard data. The start bit in the serial stream causes an NMI to be generated. The 8088 then reads the 8253 timer to determine when to interrogate the

serial stream. After de-serialization the NMI service-routine does a 'Read' from hex A0 to clear the NMI latch.

During certain time-critical operations, such as diskette I/O, the processor will mask 'off' the NMI interrupt. Keyboard inputs during this time cannot be serviced. A keyboard latch is provided so that at the end of such operations the processor will determine whether any keys were pressed and take appropriate actions. The keyboard latch is 'set' by any key being pressed and is 'reset' by 'Reading' the NMI port. (No data is presented to the microprocessor during this 'Read'.) Keyboard latch data is available to the processor at bit PCO of the 8255 PPI.

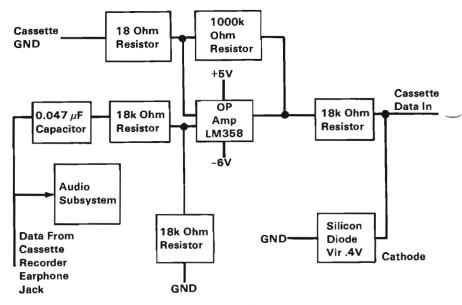

Notes:

Cassette Interface

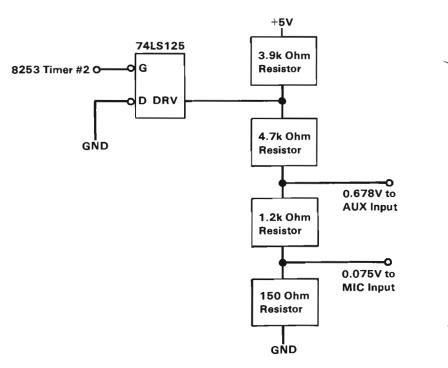

The cassette interface is controlled through software. An output from the 8253 timer controls the data to the cassette recorder through the cassette connector at the rear of the system board. The cassette-input data is read by an input-port bit of the 8255A-5 programmable-peripheral-interface (PPI) (8255A-5 PC4). Software algorithms are used to generate and read cassette-data. The cassette drive- motor is controlled by Bit PB3 of the 8255. Bit PB4, which 'enables' the 7547 relay driver, must be 'low' when the motor is to be turned on. The cassette interface has a wrap feature which connects the output to the input when the motor control is 'off'. See "BIOS Cassette Logic" in Section 5 for information on data storage and retrival.

A mechanism is provided that will direct the cassette input to the audio subsystem. Please see "Sound Subsection" in Section 2.

Circuit block diagrams for the cassette-interface read, write, and motor control are illustrated in the following figures.

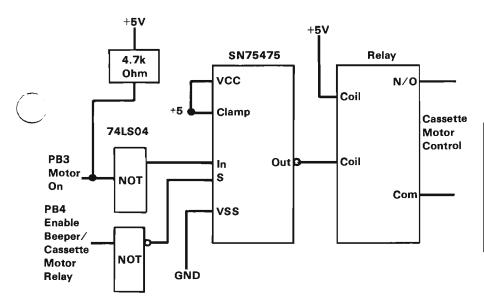

Cassette-Interface Read-Hardware Block Diagram

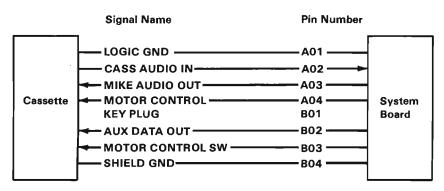

Cassette-Interface Write-Hardware Block Diagram

2-40 Cassette Interface

Cassette-Motor Control Block Diagram

Cassette Connector Specifications

Notes:

Video Color/Graphics Subsystem

The video subsystem is designed so that the IBM Color Display, composite monitors, and a home television set can be attached. It is capable of operating in black-and-white or color. It provides three video ports: a composite-video, a direct-drive, and a connector for an RF modulator to be used with home televisions. In addition, it contains a light pen interface.

Note: The IBM Personal Computer Monochrome Display cannot be used with the PCjr system.

Note: An IBM Connector for Television option must be obtained to attach a home TV.

The subsystem has two basic modes of operation: alphanumeric (A/N) and all points addressable graphics (APA). Additional modes are available within the A/N and APA modes.

In the A/N mode, the display can be operated in either a 40-column by 25-row mode for a low-resolution display home television, or an 80-column by 25-row mode for high-resolution monitors. In both modes, characters are defined in an 8-wide by 8-high character box and are 7-wide by 7-high, with one line of descender. Both A/N modes can operate in either color or black-and-white.

In the A/N black-and-white mode, the character attributes of reverse video, blinking, highlighting and gray shades are available.

In the A/N color mode, sixteen foreground-colors and sixteen background-colors are available for each character. In addition, blinking on a per-character basis

is available. When blinking is used, only eight background-colors are available. One of 16 colors, or gray shades can be selected for the screen's border in all A/N modes.

In both A/N modes, characters are formed from a ROM character-generator. The character generator contains dot patterns for 256 different characters. The character set contains the following major groupings of characters:

- 16 special characters for game support
- 15 characters for word-processing editing support
- 96 characters for the standard-ASCII-graphics set
- 48 characters for foreign-language support
- 48 characters for business block-graphics (allowing drawing of charts, boxes, and tables using single or double lines)
- 16 selected Greek symbols
- 15 selected scientific-notation characters

In the APA mode, there are three resolutions available: a low-resolution mode (160 PELs [Picture ELements] by 200 rows), a medium-resolution mode (320 PELs by 200 rows), and a high-resolution mode (640 PELs by 200 rows).

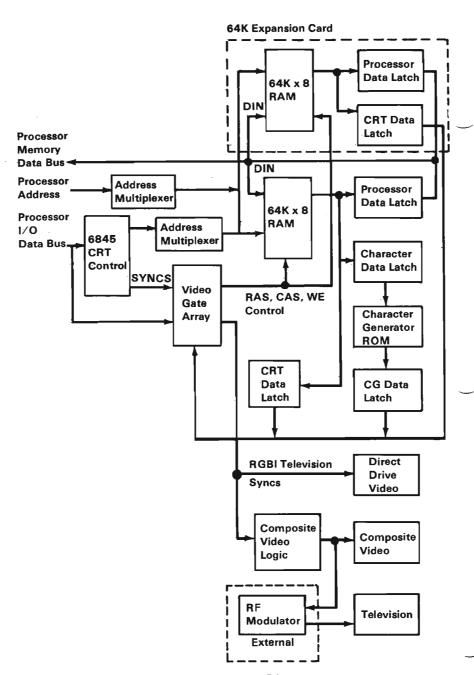

Different color modes exist within each of the APA resolutions. Two, four, or sixteen colors are available in APA color, and two, four, or sixteen gray shades are available in APA black-and-white.

One of sixteen colors, or grey shades can be selected for the screen's border in all APA modes.

The direct drive, composite video and RF Modulator connector are right-angle-mounted connectors extending through the rear of the system unit.

The video color/graphics subsystem is implemented using a Motorola 6845 CRT controller device and a Video Gate Array (VGA) (LSI5220). The video subsystem is highly programmable with respect to raster and character parameters. Thus many additional modes are possible with the proper programming.

The following figure shows a block diagram of the video color/graphics subsystem.

Video Color/Graphic Subsystem Block Diagram

Major Components Definitions

Motorola 6845 CRT Controller

This device provides the necessary interface to drive a raster-scan CRT. Additional information about this component is provided in publications listed in "Bibliography".

Storage Organization

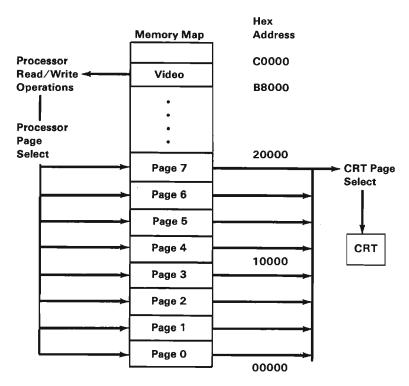

The base video-color/graphics-subsystem accesses 64K bytes of read/write memory (RAM). A 64KB Memory and Display Expansion can be added to increase the amount of system RAM to 128K bytes. This memory-storage area serves two functions; as the video-display buffer and as the system processor is (8088) main-RAM.

The RAM is located at address hex 0000 and is either 64K bytes or 128K bytes with the memory expansion option. The 8088 can access the memory by reading from and writing to address locations hex 00000 to 1FFFF or by reading from or writing to the 16K-byte region starting at address hex B8000. The page affected by a read or write operation is determined by the processor's page register. The processor can access the RAM at any time in all modes with no adverse effect to the video information. The page that the video information is taken from is determined by the CRT page register.

The processor and CRT page registers are write only registers and can be changed at any time. These registers allow the processor to work in one page while the display is displaying another page. The processor can switch pages at the vertical-retrace time. This will aid animation on the video color/graphics subsystem.

Also, since all 128K bytes of read/write memory are available for display purposes, the application can use as little or as much memory as needed for the display.

The following figure is a map of the video color/graphics subsystem.

Video Color/Graphics Subsystem Memory Map

Bandwidth

The video bandwidth is either 3.5, 7 or 14 MHz depending on the mode of operation. The processor bandwidth is the same for all modes. The processor is allowed one cycle every 1.1 microseconds. An average of two wait states will be inserted in a processor RAM read cycle, because the average latency time for the processor to get a cycle is 560 ns and the cycle time is 350 ns. There is no performance penalty for redirecting processor reads and writes through the B8000 - BFFFF address area.

Character Generator

The ROM character-generator consists of 2K bytes of storage which cannot be read from, or written to under software control. It is implemented with a MCM68A316E or equivalent. Its specifications are 350 ns access, 350 ns cycle static operation. The device is pin compatible with 2716 and 2732 EPROMS.

Video Gate Array

A CMOS gate array is used to generate storage-timing (RAS, CAS, WE), direct-drive, composite-color and status signals. See "Video Gate Array" later in this section.

Palette

The video color/graphics subsystem contains a 16-word by 4-bit palette in the Video Gate Array which takes PEL (Picture ELement) information from the read/write memory and uses it to select the color to display. This palette is used in all A/N and APA modes. Any input to the palette can be individually masked 'off' if a mode does not support the full complement of 16 colors. This masking allows the user to select a unique palette of colors whenever any mode does not support all 16 colors.

In two-color modes, the palette is defined by using one bit (PA0), with the following logic:

Palette Address Bit	
PA0	Function
O 1	Palette Register 0 Palette Register 1

Palette Logic (1 of 3)

In four-color modes, the palette is defined by using two bits (PA1 and PA0), with the following logic:

Palette A	dress Bits	
PA1	PA0	Function
0 0 1 1	0 1 0 1	Palette Register 0 Palette Register 1 Palette Register 2 Palette Register 3

Palette Logic (2 of 3)

In sixteen-color modes, the palette is defined by using four bits (PA3, PA2, PA1, and PA0), with the following logic:

Pale	ette A	dress	Bits	
PA3	PA2	PA1	PA0	Function
0	0	0	. 0	Palette Register 0
0	0	0	1	Palette Register 1
0	.0	1	0	Palette Register 2
0	0	1	1	Palette Register 3
0	1	0	0	Palette Register 4
0	1	0	1	Palette Register 5
0	1	1	0	Palette Register 6
0	1	1	1	Palette Register 7
1	0	0	0	Palette Register 8
1	0	0	1	Palette Register 9
1	0	1	0	Palette Register 10
1	0	1	1	Palette Register 11
1	1	0	0	Palette Register 12
1	1	0	1	Palette Register 13
1	1	1	0	Palette Register 14
1	1	1	1	Palette Register 15

Palette Logic (3 of 3)

The sixteen colors available to all A/N and APA modes are selected through combinations of the I (Intensity), R (Red), G (Green), and B (Blue) bits. These colors are listed in the following figure:

I	R	G	В	Color		
0 0 0	0 0 0	0 0	0 1 0	Black Blue Green		
0 0 0	0 1 1	1 0 0	1 0 1 0	Cyan Cyan Red Magenta Brown		
0 1 1	0 0	0 0	1 0 1	Light Gray Dark Gray Light Blue		
1 1 1 1 1	0 0 1 1	1 1 0 0	0 1 0 1 0	Light Green Light Cyan Pink Light Magenta Yellow		
1	1	1	1	White		

Note: The "I" bit provides extra luminance (brightness) to each available shade. This results in the light colors listed above, except for monitors that do not recognize the "I" bit.

Summary of Available Colors

Alphanumeric Modes

Every display-character position in the alphanumeric mode is defined by two bytes in the system read/write memory, using the following format:

Di	Display Character Code Byte				Attribute Byte										
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

Display Format

The functions of the attribute byte are defined by the following figure:

Attribute Function		Att	ribute	Byte	Defin	ition		
	7	6	5	4	3	2	1	0
	Fore- Ground	PA2	PA1	PA0	PA3	PA2	PA1	PA0
	Blink	Background			Foreground			
Normal	В	0	0	0	I	1	1	1
Reverse Video	В	1	1	1	Ι	0	0	0
Nondisplay (Off)	В	0	0	0	I	0	0	0
Nondisplay (On)	В	1	1	1	Ι	1	1	1

I = Highlighted Foreground (Character)

B = Blinking Foreground (Character)

Attribute Functions

Graphics Mode

The Video Color/Graphics Subsystem can be programmed for a wide variety of modes within the graphics mode. Five graphics-modes are supported by the system's ROM BIOS. They are low-resolution 16-color graphics, medium-resolution 4-color graphics, medium-resolution 16-color graphics, high-resolution 2-color graphics, and high-resolution 4-color graphics. The table in the following figure summarizes the five modes:

Graphics Mode	Horiz. (PELs)	Vert. (Rows)	Number of Colors Available (Includes Background Color)
Low-Resolution 16-Color	160	200	16 (Includes b-and-w)
Medium-Resolution 4-Color	320	200	4 Colors of 16 Available
Medium-Resolution 16-Color	320	200	16 (Includes b-and-w)
High-Resolution 2-Color	640	200	2 Colors of 16 Available
High-Resolution 4-Color	640	200	4 Colors of 16 Available

Note: The screen's border color in all modes can be set to any 1 of the 16 possible colors. This border color is independent of the screen's work area colors. In Black and White each color maps to a distinct gray shade.

Graphics Modes

Low-Resolution 16-Color Graphics

The low-resolution mode supports home-television sets, low-resolution displays, and high-resolution displays. It has the following characteristics:

- Contains a maximum of 200 rows of 160 PELs
- Specifies 1 of 16 colors for each PEL by the I, R, G, and B bits
- Requires 16K bytes of read/write memory
- Formats 2 PELs per byte for each byte in the following manner:

	•				_		
PA3	PA2	PA1	PAO	PA3	PA2	PA1	PA0
	Firs Dis PEI	play			Seco Disp PEL		

Low-Resolution 16-Color Graphics

Medium-Resolution 4-Color Graphics

The medium-resolution mode supports home-television sets, low-resolution displays, and high-resolution displays. It has the following characteristics:

- Contains a maximum of 200 rows of 320 PELs
- Selects one of four colors for each PEL
- Requires 16K bytes of read/write memory
- Supports 4 of 16 possible colors
- Formats 4 PELs per byte for each byte in the following manner:

7 6	5 4	3 2	1 0
PA1 PA0	PA1 PA0	PA1 PA0	PA1 PA0
First Display PEL	Second Display PEL	Third Display PEL	Fourth Display PEL

Medium-Resolution 4-Color Graphics

Medium-Resolution 16-Color Graphics

The medium-resolution 16-color graphics mode supports home television sets, low-resolution displays, and high-resolution displays. It has the following characteristics:

- Requires system configuration of 128K bytes of read/write memory
- Requires 32K bytes of read/write memory
- Contains a maximum of 200 rows of 320 PELs.
- Specifies 1 of 16 colors for each PEL
- Formats 2 PELs per byte for each byte in the following manner.

7	6	5	4	3	2	1	0
РАЗ	PA2	PA1	PA0	PA3	PA2	PA1	PA0
	Firs Dis PEI	play				cond play L	

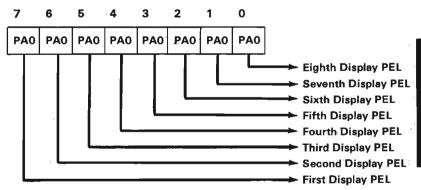

Medium-Resolution 16-Color Graphics

High-Resolution 2-Color Graphics

The high-resolution 2-color mode supports high-resolution monitors only. This mode has the following characteristics:

- Contains a maximum of 200 rows of 640 PELs
- Supports 2 of 16 possible colors.

- Requires 16K bytes of read/write memory.
- Formats 8 PELs per byte for each byte in the following manner:

High-Resolution 2-Color Graphics

High-Resolution 4-Color Graphics

The high-resolution mode is used only with high-resolution monitors. This mode has the following characteristics:

- Requires system configuration of 128K Bytes read/write memory
- Requires 32K bytes of read/write memory
- Contains a maximum of 200 rows of 640 PELs
- Selects one of four colors for each PEL
- Supports 4 out of 16 colors
- Formats 8 PELs per two bytes (consisting of one even-byte and one odd-byte) in the following manner:

Even Bytes 7 6 5 4 3 2 1 0 PA0 PA₀ PA0 PA₀ PA0 PA0 **PAO** PA₀ First Second Third **Fourth** Fifth Sixth Seventh Eighth Display Display Display Display Display Display Display Display PEL PEL PEL PEL PEL PEL PEL PEL PA₁ PA1 PA1 PA1 PA₁ PA₁ PA1 PA1 7 6 5 4 3 2 1 0

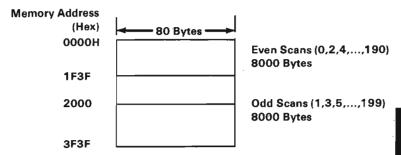

Odd Bytes

High-Resolution 4-Color Graphics

Graphics Storage Organization

For the low-resolution 16-color graphics, the medium-resolution 4-color graphics, and the high-resolution 2-color graphics, storage is organized into two banks of 8000 bytes each.

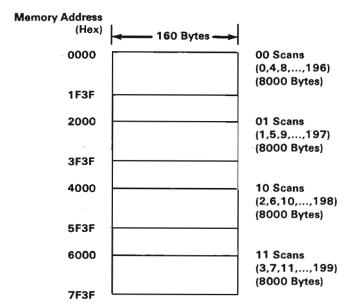

The following figure shows the organization of the graphics storage.

Graphics Storage Organization (Part 1 of 2)

Address 0000 contains PEL information for the upper-left corner of the display area.

For the medium-resolution 16-color graphics, and the high-resolution 4-color graphics modes, the graphics storage is organized into four banks of 8000 bytes each.

Graphics Storage Organization (Part 2 of 2)

Address 0000 contains PEL information for the upper-left corner of the display.

Video Gate Array

The Video Gate Array is located at I/O address hex 3DA, and is programmed by first writing a register address to port hex 3DA and then writing the data to port hex 3DA.

Any I/O 'write'-operations to hex address 3DA continuously toggle an internal address/data flip-flop. This internal flip-flop can be set to the address state by issuing an I/O 'read' instruction to port hex 3DA. An I/O 'read' instruction also 'reads' the status of the Video Gate Array. A description of each of the registers in the Video Gate Array follows.

Hex Address	Register
00	Mode Control 1
01	Palette Mask
02	Border Color
03	Mode Control 2
04	Reset
10-1F	Palette Registers

Video Gate Array Register Addresses

Mode Control 1 Register

This is a 5-bit 'write'-only register, it cannot be 'read'. Its address is 0 within the Video Gate Array. A description of this register's bit functions follows.

Bit 0	+HIBW/-LOBW
Bit 1	+Graphics/-Alpha
Bit 2	+B/W
Bit 3	+Video Enable
Bit 4	+16 Color Graphics

Mode Control 1 Register

high-bandwidth modes. These modes are all modes which require the 64KB Memory and Display Expansion for a system total of 128K bytes of read/write memory. The high bandwidth modes are the 80 by 25 alphanumeric mode, the 640 by 200 4-color graphics mode, and the 320 by 200 16-color graphics mode. This bit is 'low' (0) for all low-bandwidth modes.

Bit 1 This bit is 'high' (1) for all graphics modes and is 'low' (0) for all alphanumeric modes.

Bit 2 When this bit is 'high' (1), the composite-video color-burst and chrominance are disabled, leaving only the composite intensity-levels for gray shades. When this bit is 'low' (0), the composite-video color is 'enabled'. This

bit should be set 'high' for highresolution black-and-white display applications.

Note: This bit has no effect on direct-drive colors.

Bit 3 When this bit is 'high' (1), the video signal is 'enabled'. The video signal should be 'disabled' when changing modes. When the video signal is 'disabled', the screen is forced to the border color.

Bit 4 This bit must be 'high' (1) for all 16-color graphics-modes. These modes are the 160 by 200 16-color graphics-mode and the 320 by 200 16-color graphics-mode.

Palette Mask Register

This is a 4-bit write-only register, it cannot be 'read'. Its address in the Video Gate Array is hex 01. A description of this register's bit functions follows.

Bit 0	-Palette Mask 0
Bit 1	-Palette Mask 1
Bit 2	-Palette Mask 2
Bit 3	-Palette Mask 3

Palette Mask Register

When bits 0-3 are 0, they force the appropriate palette address to be 0 regardless of the incoming color

information. This can be used to make some information in memory a 'don't care' condition until it is requested.

In the 2-color and 4-color modes, the palette addresses should be 'masked' because only 1 or 2 color-lines contain valid information. For 4-color modes, the palette mask register should contain a hex 03 and, for 2-color modes, it should contain a hex 01.

Border Color Register

This is a 4-bit 'write'-only register, it cannot be 'read'. Its address in the Video Gate Array is hex 02. The following is a description of the register's bit functions:

Bit Number	Function
0	+ B (Blue) Border Color Select
1	+ G (Green) Border Color Select
2	+ R (Red) Border Color Select
3	+ I (Intensity) Border Color Select

Border Color Register

A combination of bits 0-3 selects the screen-border color as one of 16 colors, as listed in the "Summary of Available Colors" table in this section.

Mode Control 2 Register

This is a 4-bit, 'write'-only register, it cannot be 'read'. Its address inside the Video Gate Array is hex

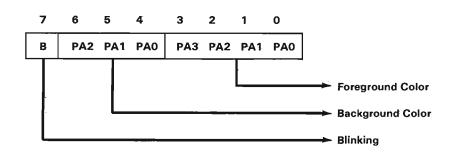

03. The following is a description of the register's bit functions:

Bit Number	Function
0	- Reserved = 0
1	+ Enable Blink
2	- Reserved = 0
3	+ 2-Color Graphics

Mode Control 2 Register

Bit 0 This bit is reserved, but should always be programmed as a 0.

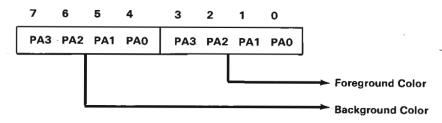

Bit 1 When this bit is 'high' (1) in the alphanumeric mode, the attribute byte has the following definition:

Where PA0 to PA3 are palette addresses.

Attribute Byte Definition (Part 1 of 2)

If the enable-blink bit is 'off' in the alphanumeric mode, the attribute byte takes on the following definition:

Attribute Byte Definition (Part 2 of 2)

If the enable-blink bit is on in a graphics mode, the high-order address of the palette (PA3) is replaced with the character-blink rate. This causes displayed colors to switch between two sets of colors.

If the colors in the lower half of the palette are the same as in the upper half of the palette, no color changes will occur. If the colors in the upper half of the palette are different from the lower half of the palette, the colors will alternately change between the 2 palette colors at the blink rate.

Only eight colors are available in the 16-color modes when using this feature. Bit 3 of the palette mask has no effect on this mode.

Bit 2 This bit is reserved, but should always be programmed as a 0.

Bit 3 This bit should be 'high' (1) when in the 640 by 200 2-color graphics-mode. It should be 'low' (0) for all other modes.

Reset Register

This is a 2-bit 'write'-only register, it cannot be 'read'. Its address inside the Video Gate Array is hex 04. The following is a description of the register's bit functions:

Bit 0 +Asynchronous Reset Bit 1 +Synchronous Reset

Reset Register

Bit 0

When 'high' (1), this bit will issue an 'asynchronous reset' to the Video Gate Array. This will cause all memory cycles to stop and all output signals to be tri-stated. The 'asynchronous reset' should only be issued once at the system power-on time. This bit should be 'high' (1), the Video Gate Array and the 6845 programmed, and then it should be 'low' (0).

The system read/write memory (RAM) will not work until this power-on sequence is finished. After this power-on sequence, subsequent 'resets' should be 'synchronous resets'.

Note: Issuing an 'asynchronous reset' can cause the contents of RAM to be destroyed.

Bit 1 When 'high' (1), this bit will issue a 'synchronous reset' to the Video Gate Array. This will cause all memory cycles to stop and all output signals to stop. Bit 1 should be 'low' (0) before changing modes.

Before issuing a 'synchronous reset', the program should read 256 locations in RAM as every other location in 512 locations. The program should then issue the 'synchronous reset' and change the mode. This changes the Video Gate Array mode-control registers and the 6845 registers.

Next, the 'synchronous reset' should be removed and the 256 RAM locations should be 'read' again as above. This procedure will ensure system RAM data-integrity during mode changes. 'Synchronous resets' need only be issued when changing between high-bandwidth, and low- bandwidth modes. (Bit 0 in mode control 1 register)

Note: No accesses to RAM can be made while the video gate array is in a 'reset' state. 'Resets' must be done from code in ROM or EPROM's.

Palette Registers

There are sixteen 4-bit-wide palette-registers. These registers are 'write'-only, they cannot be 'read'. Their addresses in the Video Gate Array are from hex 10 to 1F.

Palette address hex 10 is accessed whenever the color code from memory is a hex 0, address hex 11 is accessed whenever the color code from memory is a hex 1, and so forth. A description of the color codes is in "Summary of Available Colors" in this section.

Note: The palette address can be 'masked' by using the palette mask register.

The following is a description of the register's bit functions:

Bit Number	Function
0	+ Blue
1	+ Green
2	+ Red
3	+ Intensity

Palette Register Format

When loading the palette, the video is 'disabled' and the color viewed on the screen is the data contained in the register being addressed by the processor.

When the program has completed loading the palette, it must change the hex address to some address less than hex 10 for video to be 'enabled' again.

If a programmer does not wish a user to see the adverse effects of loading the palette, the palette should be loaded during the vertical-retrace time. The program must modify the palette and change the video gate array address to less than hex 10 within the vertical-retrace time. A vertical-retrace interrupt and a status bit are provided to facilitate this procedure.

Status Register

This is a 5-bit 'read'-only register, it cannot be 'written'. The internal address of the video gate array is a 'don't care' condition for the status-register read-operation. A description of the register's bit functions follows:

Bit 0	+Display Enable
Bit 1	+Light Pen Trigger Set
Bit 2	-Light Pen Switch Made
Bit 3	+Vertical Retrace
Bit 4	+Video Dots

Status Register

- Bit 0 When 'high' (1), this bit indicates video is being displayed.
- Bit 1 When 'high' (1), this bit indicates that a positive- going edge from the light pen input has set the light pen trigger. This trigger is 'low' (0) upon a system power-on, and may also be cleared by performing an I/O 'Out' command to address hex 3DB. No specific data is required, this action is address-activated.
- Bit 2 This bit indicates the status of the light pen switch. The switch is not latched or debounced. When this bit is 'low' (0), the light pen switch is 'on'.
- Bit 3 When 'high' (1), this bit indicates the vertical retrace is 'active'.

Bit 4 When 'high' (1), this bit indicates that video-dot information is available. The two low-order bits of the address register determine the video-dot information presented through the following logic:

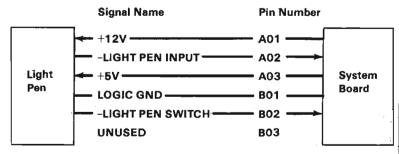

Address Register Bit 1	Address Register Bit 0	Video Dot Information Selected
0	0	Blue
0	1	Green
1	0	Red
1	1	Intensity

Address Register

This bit is provided for testing purposes. It verifies that video is occurring properly, and that the palette registers and all other 'write'-only registers are operating correctly.

Light Pen

A light pen can be used on the PCjr by connecting it to the six-pin connector for light pens on the back of the system board.

Connector Specifications

Note: The light pen interface is set for RGBI (Red, Green, Blue, Intensity). Due to timing differences between different displays (Different phosphors take longer to turn on, and different circuits take longer to accomplish their task.) the row, column value returned from the CRT can vary. This difference must be compensated for through software.

Programming Considerations

Programming the 6845 CRT Controller

The 6845 has 19 accessible, internal registers, which are used to define and control a raster-scanned CRT display. One of these registers, the Index Register, is actually used as a pointer to the other 18 registers. It is a 'write'-only register, which is loaded from the processor by executing an 'Out' instruction to I/O address hex 3D4. The five least-significant-bits of the I/O bus are loaded into the Index Register.

In order to load any of the other 18 registers, the Index Register is first loaded with the necessary pointer; then the Data Register is loaded with the information to be placed in the selected register. The Data Register is loaded from the processor by executing an 'Out' instruction to I/O address hex 3D5.

The following table defines the values that must be loaded into the 6845-CRT-Controller registers to control the different modes of operation supported by the attachment:

Hex	Register		Register		Alphar	umeric	Low/High Band Width
Addr.	#	Туре	Units	I/O	40x25	80x25	Graphics
0	R0	Horizontal Total	Char.	Write Only	38	71	38/71
1	R1	Horizontal Display	Char.	Write Only	28	50	28/50
2	R2	Horizontal Sync Position	Char.	Write Only	2C	5A	2B/56
3	R3	Horizontal Sync Width	Char.	Write Only	06	0C	06/0C

6845 Register Table (Part 3 of 3)

CRT/Processor Page Register

This register is an 8-bit 'write'-only register, that cannot be read. Its address is hex 3DF. The following is a description of the Register functions.

Bit Number	Description
0	CRT Page 0
1	CRT Page 1
2	CRT Page 2
3	Processor Page 1
4	Processor Page 2
5	Processor Page 3
6	Video Address Mode 0
7	Video Address Mode 1

CRT/Processor Page Register (Part 1 of 2)

CRT Page 0-2

These bits select which 16K byte memory-page between 00000 to hex 1FFFF is being displayed. If there is no expansion RAM in the system, the high- order bit is a 'don't care', and only 4 pages are supported. For graphics modes which require 32K bytes the low-order bit is a 'don't care'.

Processor Page 0-2

These bits select the 16K byte memory-page region where memory cycles to B8000 are redirected. If there is no expansion RAM installed in the system, the high-order bit is a 'don't care' and only 4 pages are supported.

Video Adr Mode 0-1

These bits control whether the row scan addresses are used as part of the memory address. These should be programmed as follows:

Video Address Mode		
1 (Bit 7)	0 (Bit 6)	Resulting Modes
0	0	All Alpha Modes
0	1	Low-Resolution-Graphics Modes
1	1	High-Resolution-Graphics Modes
1	0	Unused, Reserved

CRT/Processor Page Register (Part 2 of 2)

The following I/O devices are defined on the video color/graphics subsystem:

Hex Address	A9	A8	A7	A6	A5	A4	A 3	A2	A1	A0	Function of Register
3DA	1	1	1	1	0	1	1	0	1	0	Gate Array Address and Status Register

x = "don't	care	" c	ond	itio	n						

Video I/O Devices

Mode Selection Summary

Four registers of the Video Gate Array allow the user to access all the alphanumeric and graphics modes supported by the system ROM BIOS. The following table summarizes the modes and their register settings:

	Video Gate Array Reg.				
Mode	00	01	02	03	
40 by 25 Alphanumeric Black-and-White	0C	0F	00	02	
40 by 25 Alphanumeric Color	08	0F	00	02	
80 by 25 Alphanumeric Black-and-White	0D	0F	00	02	
80 by 25 Alphanumeric Color	09	0F	00	02	
160 by 200 16-Color Graphics	1 A	0F	00	00	
320 by 200 4-Color Graphics	0A	03	00	00	
320 by 200 4-Shade Black-and-White	0E	03	00	00	
320 by 200 16-Color Graphics	1B	0F	00	00	
640 by 200 2-Color Graphics	0E	01	00	08	
640 by 200 4-Color Graphics	0B	03	00	00	

Note: All values are given in hexadecimal.

Mode Summary

Sequence of Events for Changing Modes

- 1. Determine the mode of operation.
- 2. Reset the 'video enable' bit in the Video Gate Array to disable video.
- 3. Program the 6845 CRT Controller to select the mode.

Read 256 bytes of memory Reset gate array

4. Program the Video Gate Array registers.

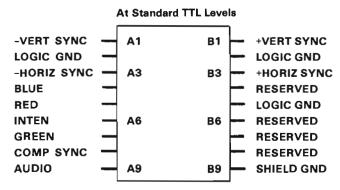

Remove gate-array reset Read 256 bytes of memory

5. Re-enable video.

Note: The gate array needs to be reset only when changing the high-bandwidth/low-bandwidth register.

Interrupt Information

The Video Gate Array uses interrupt level 5 of the Intel 8259 to provide the vertical retrace interrupt to the system.

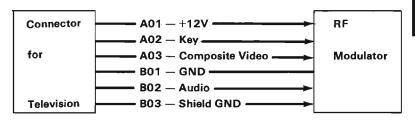

Connector Specifications

The direct-drive signals are standard TTL levels except the audio output which is a 1V peak-to-peak signal biased at 0V which can drive a 10K ohm or greater input-impedence.

Connector Specifications

The composite-video signal is 1V peak to peak biased at .7V with a 75 ohm load.

Television Connector Specifications

The Connector for Television connector has the composite-video signal at IV peak to peak biased at .7V with a 75 ohm load. The connector also has the audio output which is IV peak-to-peak signal biased at 0V which can drive a 10K ohm or greater input impedence.

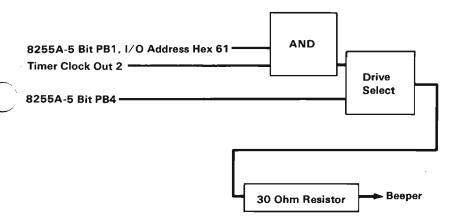

Notes:

Beeper

The system beeper is a small, piezoelectric- speaker, which can be driven from one or both of two sources. The two sources are:

- The 8255A-5 PPI output-bit PB1
- A timer clock out of an 8253-5 timer which has a 1.19 MHz-clock input. The timer gate is also controlled by an 8255-5 outport bit PB0.

Note: The TI76496 Sound Generator cannot be directed through the beeper.

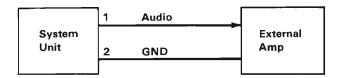

Beeper Block Diagram

Notes:

Sound Subsystem

The nucleus of the sound subsystem is an analog multiplexer (mpx) which allows 1 of 4 different sound sources to be selected, amplified, and sent to the audio outputs. The mpx and amplifier are configured so the amplifier's gain is unique to and consistent with each sound source. This provides a consistent level of output with any of the sound sources. The output of the amplifier is supplied to the IBM Connector for Television interface and external-amplifier interface. If an external speaker is used, an external amplifier must be used to drive it. The amplifier is configured as a single-pole low pass filter with a 3 dB cut-off frequency of 4.8 kHz. This filter is used to "round" off the corners of the square-wave signals. BIOS Power-on will initialize the sound subsystem to use the 8253 programmable-timer mode.

Connector Specifications

The audio output is a 1V peak-to-peak signal biased at 0V. It can drive a 10k ohm or greater input-impedence.

Source	Port PB6	Bits PB5
Complex Sound Generator (TI 76496)	1	1
Programmable Timer (8253)	0	0
Cassette Audio	0	1
I/O Channel Audio	1	0

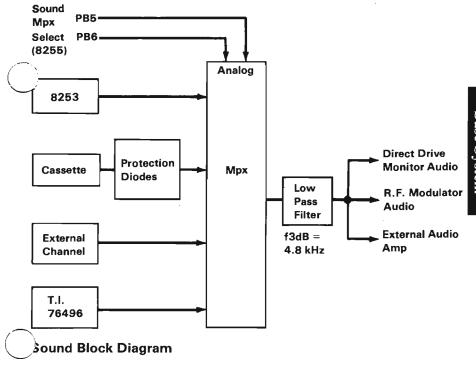

Port bits PB5 and PB6, of the 8255, control which source is selected.

Sound Sources

Complex Sound Generator

The Complex Sound Generator chip (SN76496N) has 3 programmable frequencies which may be mixed to form chords and a white noise generator which may also be mixed for special effects. Each of the 3 channels as well as the white noise generator can be independently attenuated. The processor controls the sound chip by writing to port hex CO.

The Sound Generator is described in greater detail later in this section. More information can be obtained by referring to Texas Instruments' data sheets and application notes.

Audio Tone Generator

Features

- 3 Programmable Tone-Generators
- Programmable White Noise
- Programmable Attenuation
- Simultaneous Sounds
- TTL Compatible
- 3.579 MHz Clock Input
- Audio Mixer

Processor to Sound-Generator Interface

The system microprocessor communicates with the SN76496N through the 8 data lines and 3 control lines

(WE, CE and READY). Each tone generator requires 10 bits of information to select the frequency and 4 bits of information to select the attenuation. A frequency update requires a double-byte transfer, while an attenuator update requires a single-byte transfer.

If no other control registers on the chip are accessed, a tone generator may be rapidly updated by initially sending both types of frequency and register data, followed by just the second byte of data for succeeding values. The register address is latched on the chip, so the data will continue going into the same register. This allows the 6 most-significant bits to be quickly modified for frequency sweeps.

Control Registers

The sound generator has 8 internal registers which are used to control the 3 tone generators and the noise source. During all data transfers to the sound generator, the first byte contains a 3-bit field which determines the destination control register. The register address codes are as follows:

Regist	er Addres	s Field	
MSB R0	R1	LSB R2	Destination Control Register
0	0	0	Tone 1 Frequency
0	0	1	Tone 1 Attenuation
0	1	0	Tone 2 Frequency
0	1	1	Tone 2 Attenuation
1	0	0	Tone 3 Frequency
1	0	1	Tone 3 Attenuation
1	1	0	Noise Control
1	1	1	Noise Attenuation

Register Address Field

7		Re	g. Ac	ldr.		Low		
-1	1	RO	R1	R2	F6	F7	F8	·F9
	Bit 0 MSB			First	Byte)		Bit 7 LSB

			Н	igh C	ata		
0	X	F0	F1	F2	F3	F4	F5
Bit 0 MSB		S	econ	d By	te		Bit 7 LSB

Frequency (Double or Single Byte Transfer)

Frequency Generation

Each tone generator consists of a frequency-synthesis section and an attenuation section. The frequency-synthesis section requires 10 bits of information (hex F0-F9) to define half the period of the desired frequency (n). Hex F0 is the most-significant bit and hex F9 is the least-significant bit. This information is

loaded into a 10-stage tone-counter, which is decremented at an N/16 rate where N is the input-clock frequency. When the tone counter decrements to 0, a borrow signal is produced. This borrow signal toggles the frequency flip-flop and also reloads the tone counter. Thus, the period of the desired frequency is twice the value of the period register.

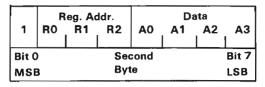

The frequency can be calculated by the following:

$$f = N_{\underline{32n}}$$

where N = ref clock in Hz (3.579 MHz)

n = 10-bit binary-number

Attenuator

Update Attenuation (Single Byte Transfer)

The output of the frequency flip-flop feeds into a four-stage attenuator. The attenuator values, along with their bit position in the data word, are shown in the following figure. Multiple-attenuation control-bits may be 'true' simultaneously. Thus, the maximum theoretical attenuation is 28 dB typically.

		Bit I	Position	
MSB A0	A1 -	A2	LSB A3	Weight
0	0	0	1	2dB
0	0	1	0	4dB
0	1	0	0	8dB
1	0	0	0	16db
1	1	1	1	OFF

Attenuator Values

Noise Generator -

	R	eg. Ad	ldr.				
1	R0 1	R1 1	R2 0	×	FB	SH NF0	
MSB							LSB

Update Noise Source (Single Byte Transfer)

The noise generator consists of a noise source and an attenuator. The noise source is a shift register with an exclusive-OR feedback-network. The feedback network has provisions to protect the shift register from being locked in the zero state.

FB	Configuration
0	Periodic Noise White Noise

Noise Feedback Control

Whenever the noise-control register is changed, the shift register is cleared. The shift register will shift at one of four rates as determined by the two NF bits. The fixed shift-rates are derived from the input clock.

В	its	
NF0	NF1	Shift Rate
0	0	N/512
0	1	N/1024
1	0	N/2048
1	1	Tone Generator #3 Output

Noise Generator Frequency Control

The output of the noise source is connected to a programmable attenuator.

Audio Mixer/Output Buffer

The mixer is a conventional operational-amplifier summing-circuit. It will sum the three tone-generator

outputs, and the noise-generator output. The output buffer will generate up to 10 mA.

Data Transfer

The sound generator requires approximately 32 clock cycles to load the data into the register. The open collector READY output is used to synchronize the microprocessor to this transfer and is pulled to the false state (low voltage) immediately following the leading edge of CE. It is released to go to the true state (external pull-up) when the data transfer is completed.

This will insert approximately 42 wait states (8.9 μ s) for each data transfer.

Warning: Do not attempt to issue an I/O read operation to the TI76496 port (COH). Such an operation will cause the system to hang indefinitely.

Note: If DMA is added to the system on the I/O channel, I/O WRITES to the 76496 will increase the latency time.

Notes:

Infra-Red Link

The infra-red link provides cordless communications between the keyboard and the system unit. Two infra-red-emitting diodes, mounted in the keyboard, transmit coded information to the system unit. The keyboard transmitter is fully discussed in "Cordless Keyboard" in this section. The infra-red receiver, which is located in the system unit, has an infra-red-sensitive device that demodulates the signal transmitted from the keyboard and sends it to the system.

Infra-Red Receiver

The receiver card measures 57.15 mm wide by 63 mm (2.25 in. by 2.50 in.) long. The infra-red receiver is mounted on the system board, component-side down, with two snap-in-type standoffs. Signal output and power input is through an 8-pin connector, located at the rear of the infra-red receiver. The infra-red-sensitive device is located on the front of the board and receives its input through an opening in the front of the system unit's cover. There is also an infra-red transmitter mounted on the receiver board for diagnostic purposes.

Functional Description

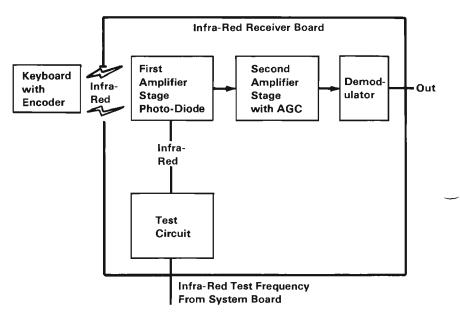

The following figure is the Infra-Red Receiver Block Diagram. During keyboard operation, the emitted light is modulated, transmitted, and received in the following sequence:

1. A key is pushed.

- 2. The data stream is sent using the infra-red-emitting diodes.
- 3. The receiver amplifies and processes the signal.
- 4. The demodulated signal is sent to the system board.

The signal received consists of an infra-red-light transmission modulated at 40 kHz.

An input is available (I/R Test Frequency) to the system for receiver-circuit-operational verification.

Infra-Red Receiver Block Diagram

Application Notes

The Infra-Red Receiver Board can serve as a general-purpose infra-red-receiver, however, the

demodulator timings are tailored to the needs of the system.

Programming Considerations

The serially-encoded word is software de-serialized by the 8088 processor on the system unit. The leading edge of the start bit will generate a non-maskable interrupt (NMI). Once the processor enters the NMI routine to handle the descrialization, the keyboard-data line is sampled and the processor waits to sample the trailing edge of the start bit. When the trailing edge of the start bit is sampled, the processor will wait for 310 μs and sample the first half of the first data bit. This delay causes the processor to sample in the nominal center of the first half of the first data bit. The processor then samples the keyboard data every halfbit cell-time. The sampling interval is 220 us. The processor samples each half-bit-sample 5 times and will determine the logical level of the sample by majority rule. This enables the processor to discriminate against transient glitches and to filter out noise. The 8088 processor utilizes one 8255 PPI bit (PORT C BIT 6) and shares one 8253 timer channel (CHANNEL 1) to do the software de-serialization of the keyboard data. See the "Cordless Keyboard" in this section for more information on the data-transmission protocal.

Detectable Error Conditions

Errors	Cause
Phase Errors	The 1st half of the bit-cell sample is not equal to the inverse of the 2nd half
Parity Errors	of the bit-cell sample. The received encoded word did not
•	maintain odd parity.

Note: Errors will be signaled by the processor with a short tone from the audio alarm or external speaker.

Operational Parameters

The operational distance from infra-red devices to the system should not exceed 6.1 meters (20 feet) (line-of-sight). Operational efficiency can be impaired by outside sources. These sources are, excessively-bright lights, and high-voltage lines, which include some TV sets. High-energy sources will generally cause an audible alarm within the system unit. These sources may downgrade the operational distance from the keyboard to the system. A keyboard cable is recommended if the above interference conditions are not controllable.

Infra-Red Connector Specifications

IBM PCjr Cordless Keyboard

The keyboard is a low-profile, 62-key, detached keyboard with full-travel keys. The keys are arranged in a standard typewriter layout with the addition of a function key and cursor-control keys. The keybuttons are unmarked; however, an overlay is used to provide the keys' functional descriptions.

The following figure shows the layout of the cordless keyboard.

The keyboard is battery powered and communicates to the system unit with an infra-red (IR) link. The infra-red link makes the remote keyboard a truly portable hand-held device. An optional-cord connection to the system unit is available. Power is sent to the keyboard and serially-encoded data received by the system unit through the optional cord. When connected, the cord's keyboard-connector removes the battery power and the -CABLE CONNECT signal disables the infra-red-receiver circuit. The disabling of the circuit also allows other infrared devices to be used

without interfering with the system. The data which is received through the IR link or by the cord, have the same format.

The keyboard interface is designed to maximize system-software flexibility in defining keyboard operations such as shift states of keys, and typematic operation. This is accomplished by having the keyboard return scan codes rather than American National Standard Code for Information Interchange (ASCII) codes. The scan codes are compatible with Personal Computer and Personal Computer XT scan codes at the BIOS interface level. All of the keys are typematic and generate both a make and a break scancode. For example, key 1 produces scan code hex 01 on make and code hex 81 on break. Break codes are formed by adding hex 80 to the make codes. The keyboard I/O driver can define keyboard keys as shift keys or typematic, as required by the application.

The microprocessor in the keyboard performs keyboard scanning, phantom-key detection, key debounce, buffering of up to 16 key-scan-codes, and transfer of serially-encoded data to the system unit. The keyboard microprocessor is normally in a standby power-down mode until a key is pressed. This causes the microprocessor to scan the keyboard. The microprocessor then transmits the scan code, and re-enters the power-down mode if its buffer is empty and no keys are pressed.

The keyboard electronics is designed with low-power CMOS integrated-circuitry for battery power operation. Four AA-size batteries are required. Because the keyboard is normally in the standby power-down mode, which uses very little power, no on/off switch is needed.

Unlike other keyboards in the IBM Personal Computer family, the IBM PCjr Cordless Keyboard has phantom-key detection. Phantom-key detection occurs when invalid combinations of three or more keys are pressed simultaneously, causing a hex 55 scan-code to be sent to the keyboard's processor. The phantom-key scan-code instructs the keyboard's processor to ignore all of the keys that were pressed at that time. BIOS ignores the resulting scan-code that is sent to it.

The keyboard-cord connector provides a batterydisconnect function and also disables the infra-redtransmission circuitry when the mating plug for the modular jack is connected.

Note: See "Keyboard Encoding and Usage" in Section 5, for scan codes and further information.

Transmitter

Serially encoded words are transmitted to the system unit using the Infra-Red Link or the cable link. Encoded words are sent to the system unit with odd parity. Both the Infra-Red Link and the cable link use biphase serial-encoding and each is a simplex link.

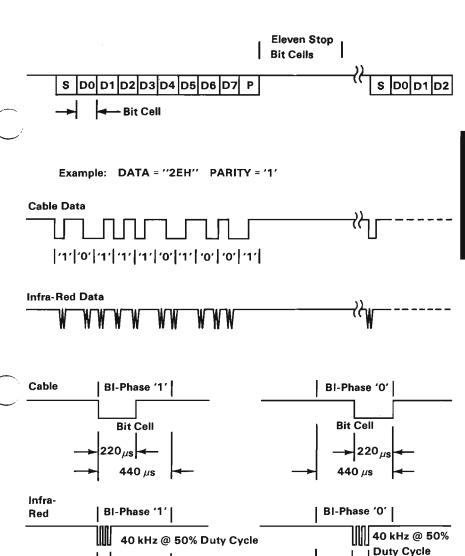

The 80C48 microprocessor does the biphase serial encoding with a bit cell of 440 μ s. A biphase logically-encoded 1 is transmitted as logical 1 for the first half of the bit cell time and as a logical 0 for the second half of the bit cell. A biphase logically-encoded 0 is transmitted as a logical 0 for the first half of the bit cell time and as a logical 1 for the second half of the bit cell.

Each logical 1 transmission for the Infra-Red Link consists of a 40 kHz carrier burst at a 50% duty cycle.

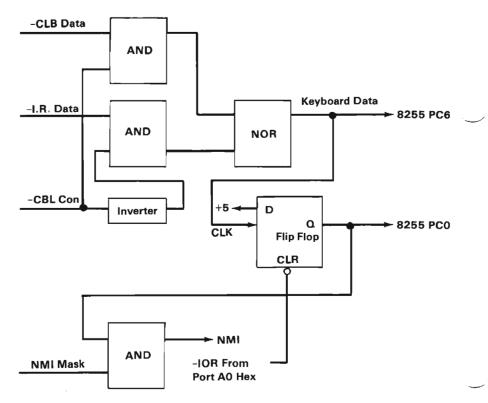

First Bit Second Bit Third Bit Fourth Bit Fifth Bit Sixth Bit Seventh Bit Eight Bit Ninth Bit Tenth Bit	Start Bit Data Bit 0 (Least Significant Bit) Data Bit 1 Data Bit 2 Data Bit 3 Data Bit 4 Data Bit 5 Data Bit 6 Data Bit 7 (Most Significant Bit) Parity Bit Stop Bit	
Eleventh Bit	Stop Bit	

Data Stream Sequence

Eleven stop bits are inserted after every scan-code transmission. This is to allow some processor bandwidth between keystrokes to honor other types of interrupts, such as serial and time-of-day.

Keyboard Transmission Timing

Keyboard Interface Logic

Program Cartridge and Interface

The Program Cartridge allows the addition of ROM to the system without removing the cover by plugging it, into either of two slots in the front of the machine.

The 48 by 72 mm (2 by 3 inch) cartridge can hold one or two 32K byte by 8 ROMS (64K bytes total) of program storage. Smaller ROMS such as the 8K byte by 8 modules can be used in the cartridge. When a smaller module is used, the higher address lines are not used. To allow two smaller modules to be mapped to adjacent memory segments, each module's contents is addressed to multiple adjacent-memory segments, within the addressable range of the module's socket (32k).

Program Cartridge Slots

The Program Cartridge is designed to plug into either of two identical slots in the front of the machine. Each slot has 15 address signals, 8 data signals, 6 chip selects, 2 control signals, and power. Cartridge selection is accomplished by the chip selects, each of which addresses one of the high 32K memory-blocks. Each cartridge uses up to two of the six chip selects. Selection is determined on the basis of the intended use of the cartridge. This is done at the factory.

Two of the chip selects are used by the internal system-ROM. These two signals can be used to allow the internal ROM to be replaced by a Program Cartridge. This allows the machine to assume a different personality from the standard machine. To use this option of mapping the internal-ROM space to a cartridge, the Base-ROM-in-Cartridge function must be inserted. This function is a factory-installed

signal-jumper manufactured into particular program-cartridges that are intended to replace the system ROM.

Note: When the cartridge is inserted or removed with the system turned on, the system will 'reset' and go through a warm power-up. Any data in the system RAM will be lost.

Cartridge Storage Allocations

A. The following conventions will be followed for "Initial Program Loadable" program cartridges:

Location	Contents 055H		
0			
1	0AAH		
2	Length		
3,4,5	Jump to Initialize Code		
6	0		
Last 2 Addresses	CRC Bytes		

Storage Conventions

- Locations 0 and 1 contain the word hex 55AA.
 This is used as a test for the presence of the cartridge during the configuration- determination portion of the power-on routines.
- Location 2 contains a length indicator representing the entire address space taken by the ROM on the cartridge. The algorithm for determining the

- contents of this byte is (length/512). The contents of this byte is used by the CRC (cyclic-redundancy-check) routine to determine how much ROM to check.
- Location 3 contains the beginning of an initialization routine that is reached by a 'Long' call during the power-on sequence. For cartridges that are 'IPL-able' (BASIC or assembler program) this routine should set the INT hex 18 vector to point to their entry points. Other types of cartridges (BASIC or whatever) should merely 'return' to the caller. Setting the INT hex 18 vector will enable transfer of control to the cartridge program by the IPL routine.
- This location 6 should be 00.
- CRC bytes: The last two locations of the address space used by the cartridge must be blank. CRC characters will be placed in these bytes when the cartridge is built. See the routine at label "CRC Check", in the BIOS listing for the CRC algorithm.
- B. The following conventions will be followed for cartridges that wish to be recognized by DOS 2.1 as containing code associated with DOS command words:

Location	Contents
0	055H
1	0AAH
2	Length
3-5	Jump to Initialize
6	Command Name Length (Offset Y-Offset Z)
Z	First Character in Command Name
Y	Last Character in Command Name
W	Word Pointing to Routine that is Jumped to if "Name" is Typed
X	Next Command Name Length or "00" if No More Command Names
Last 2 Addresses	CRC Bytes

DOS Conventions

- Locations 0 and 1 contain the word hex 55AA.

 This is used as a test for the presence of the cartridge during the configuration- determination portion of the power-on routines.
- Location 2 contains a length indicator representing the entire address space taken by the ROM on the cartridge. The algorithm for determining the contents of this byte is (length/512). The contents of this byte is used by the CRC routine to determine how much ROM to check.
- Location 3 contains a 'jump' to the initialization code for this ROM. (May just be a 'Far Return')
- Starting at location 6 may be a sequence of command name pointers consisting of 1: Count of length name, 2: Name in ASCII, and 3: Word

containing offset within this segment to the code that is entered when this name is called. There can be as many names as desired, providing that a hex 00 is placed in the count field following the last name pointer. If a cartridge has a routine called 'TEST' at location hex 0FB5 (offset from start of segment that the cartridge is in) that needs to be executed when 'test' is entered as a DOS command the entry at location 6 would be hex 04,54,45,53,54,B5,0F.

 CRC bytes: The last two locations of the address space used by the cartridge must be blank. CRC characters will be placed in these bytes when the cartridge is built. See the routine at label "CRC Check", in the BIOS listing for the CRC algorithm.

C. The following conventions will be followed for cartridges that wish to be recognized by "Cartridge BASIC" as containing interpretable-BASIC Code:

- The cartridge-chip selects must address hex D0000 since the BASIC cartridge addresses hex E0000.
 When "Cartridge BASIC" is activated, it will check for a second cartridge program at hex D0000. If the second cartridge is present and formatted properly, then the BASIC code is loaded into RAM and run.
- The format for this interpretable-BASIC code must be as follows:

Location	Contents
0	055H
1	0AAH
2	Length
3	0СВН
4	0AAH
5	055H
6	0
7	0FFH if unprotected Basic program or 0FEH if protected Basic program
8	Start of interpretable Basic code
n	0FFH Padding to next 2048 byte boundary
Last 2 Addresses	CRC Bytes

Cartridge Format

- 1. Locations 0 and 1 contain the word hex 55AA.

 This is used as a test for the presence of the cartridge during the configuration-determination portion of the power-on routines.
- 2. Location 2 contains a length indicator representing the entire address space taken by the ROM on the cartridge. The algorithm for determining the contents of this byte is (length/512). The contents of this byte is used by the CRC routine to determine how much ROM to check.
- 3. Location 3 must be hex 0CB for a 'far return' instruction.

- 4. Locations 4 and 5 contain the word hex AA55. This is used as a test for the presence of the second cartridge by "Cartridge Basic".
- 5. Location 6 must be a 0 to follow the DOS conventions.
- Location 7 can be either hex FF to indicate an unprotected BASIC program, or hex FE to indicate a protected program.
- 7. Location 8 must be the start of the BASIC program. It must be interpretable Basic and not compiled. Also, at the end of the program PAD to the next 2048 byte boundary with hex 0FF.
- 8. CRC bytes: The last two locations of the address space used by the cartridge must be blank. CRC characters will be placed in these bytes when the cartridge is built. See the routine at label "CRC Check", in the BIOS listing for the CRC algorithm.

ROM Module

The ROM modules used are 250 ns devices. Typical modules are the Mostek MK37000 and MK38000, the TMM 23256, the SY23128, and other compatible devices.

ROM Chip Select	Hex Address Space	Typical Use
CS0 CS1 CS2 CS3 CS4 CS5 CS6 CS7	X X D0000-D7FFF D8000-DFFFF E0000-E7FFF E8000-E7FFF F8000-F7FFF	Not Used Not Used Optional Cartridge ROM #2 Optional Cartridge ROM #1 Standard Cartridge ROM #2 Standard Cartridge ROM #1 System Board ROM #2 System Board ROM #1

ROM Chip Select Table

Signal	I/O	Description
A0 - A14	0	Processor Address lines A0 - A14
D0 - D7	Ι	Processor Data lines

-CS2 THRU -CS7 0

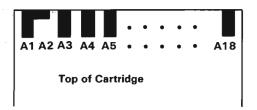

I

These chip-select lines are used to select ROM modules at different addresses. The addresses for each chip-select are shown in the ROM-chip select-table. -CS6 and -CS7 are used on the system board for BIOS, Power-On-Self-Test (POST) and cassette-basic ROMs. In order to use these chip selects on a cartridge, -BASE 1 ROM IN CARTRIDGE or -BASE 2 ROM IN CARTRIDGE must be pulled 'low'

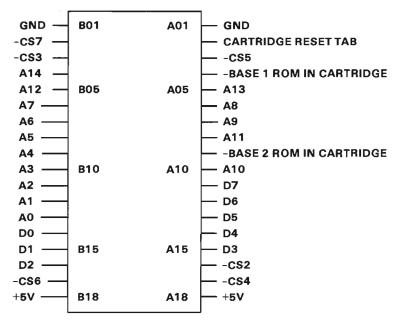

-BASE 1 ROM IN CARTRIDGE This line when pulled 'low' instructs the system board to de-gate the ROM module from hex F8000 - FFFFF on the system board. This ROM module can then be replaced by a ROM module on the cartridge by using -CS7.

-BASE 2 ROM I IN CARTRIDGE This line when pulled 'low' instructs the system board to de-gate the ROM module from hex F0000 - F7FFF on the system board. This ROM module can then be replaced by a ROM module on the cartridge by using -CS6.

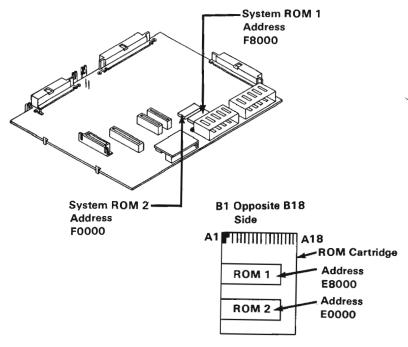

Cartridge Reset I Tab This input when 'low' causes a 'reset' to the system. The system will remain 'reset' until this line is brought back 'high'. This tab is usually wired with an L shaped land pattern to the GND at A02 which provides a momentary 'reset' when a cartridge is inserted or removed.

Momentary Reset Land

Connector Specification

Games Interface

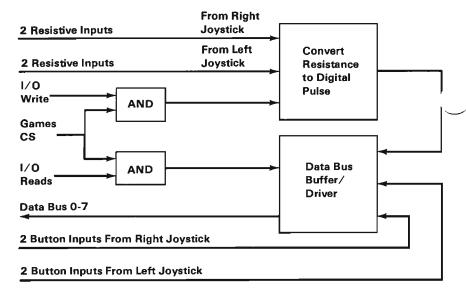

Interface Description

The Game Interface has two connectors located at the rear of the System unit for four paddles (two per connector) or two joysticks. Each connector has four input lines: two digital inputs and two resistive inputs. All the inputs are 'read' with one 'IN' from address hex 201. The interface, plus system software, converts the present resistive value to a relative paddle or joystick-position. On receipt of an output signal, four timing circuits are started. By determining the time required for the circuit to time out (a function of the resistance), the paddle or joystick position can be determined.

The four digital inputs each have a 1K ohm resistor to pull the voltage up to +5V. With no drive on these inputs, a 1 is read. For a 0 reading, the inputs must be pulled to ground.

The four resistive inputs are converted to a digital pulse with a duration proportional to the resistive load, according to the following equation:

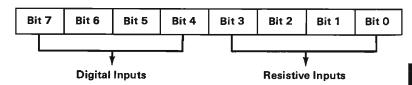

Time = 24.2 μ s + 0.011 (r) μ s Where r is the resistance in ohms

Games Interface Block Diagram

Any program application must first begin the conversion by an 'OUT' to address hex 201. An 'IN' from address hex 201 will show the digital pulse go 'high' and remain 'high' for the duration according to the resistance value. All four bits (Bit 3 through Bit 0) function in the same manner. Each bits digital pulse goes high simultaneously and resets independently according to the input resistance value.

Input from Address Hex 201

Input From Address Hex 201

Joysticks typically have one or two buttons and two variable resistances each. The variable resistances are mechanically linked to have a range from 0 to 100k ohms. One variable resistance indicates the X coordinate and the other variable resistance indicates the Y coordinate. The joysticks are attached to give the following input data:

Joystick B		Joystick A		Joystick B		Joystick A	
Button #2	Button #1	Button #2	Button #1	Coord. Y	Coord. X	Coord. Y	Coord. X
Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Joystick Input Data

The game paddles have one button each and one variable resistance each. The variable resistance is mechanically linked to have a range from 0 to 100k ohms. The paddles are attached to give the following input data.

Buttons				Cool	dinates		
Paddle D	Paddle C	Paddle B	Paddle A	Paddle D	Paddle C	Paddle B	Paddle A
Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Paddle Input Data

Pushbuttons

The pushbutton inputs are 'read' by an 'IN' from address hex 201. These values are seen on data bits 7 through 4. These buttons default to an 'open' state and are 'read' as 1. When a button is pressed, it is 'read' as 0.

Note: Software should be aware that these buttons are not debounced in hardware.

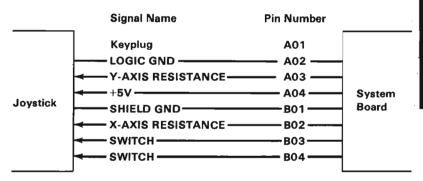

Joystick Positions

The joystick position is indicated by a potentiometer for each coordinate. Each potentiometer has a range from 0 to 100k ohms that varies the time constant for each of the four one-shots. As this time constant is set at different values, the output of the one-shot will be of varying durations.

All four one-shots are fired simultaneously by an 'OUT' to address hex 201. All four one-shot outputs

will go 'true' after the fire pulse and will remain 'high' for varying times depending on where each potentiometer is set.

These four one-shot outputs are 'read' by an 'IN' from address hex 201 and are seen on data bits 3 through 0.

Connector Specification

Notes:

Serial Port (RS232)

The PCjr serial port is fully programmable and supports asynchronous communications only. It will add and remove start bits, stop bits, and parity bits. A programmable baud-rate generator allows operation from 50 baud to 4800 baud. Five, six, seven or eight bit characters with 1, 1-1/2, or 2 stop bits are supported. A fully-prioritized interrupt-system controls transmit, receive, line status and data-set interrupts. Diagnostic capabilities provide loopback functions of transmit/receive and input/output signals.

The nucleus of the adapter is a 8250A LSI chip or functional equivalent. Features in addition to those previously listed are:

- Full double-buffering eliminates the need for precise synchronization
- Independent receiver clock input.
- Modem control functions: clear to send (CTS), request to send (RTS), data set ready (DSR), data terminal ready (DTR)
- · Even, odd, or no-parity-bit generation and detection
- False start bit detection
- Complete status reporting capabilities
- Line-break generation and detection
- Break, parity, overrun, and framing error simulation
- Full prioritized interrupt system controls

All communications protocol is a function of the system ROM and must be loaded before the adapter is operational. All pacing of the interface and control-signal status must be handled by the system software. It should be noted that Asynchronous (Async) receive operations cannot overlap diskette operation since all but the Diskette Interrupt are masked 'off' during diskette operations. If Async receive

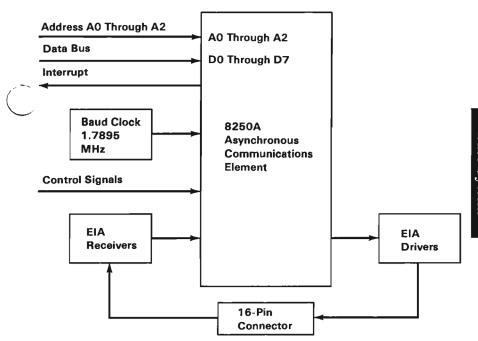

operations are going to be overlapped with keyboard receive operations, the Async Receiver rate cannot exceed 1200 baud. This is due to the processor deserialization of the keyboard. See IBM PCjr Cordless Keyboard in this section for more information.

Programming Note: Due to the read/write cycle-time of the 8250A, it is recommended that back-to-back I/O operations to the 8250A be avoided. A good Programming Technique would be to insert a short 'jump' between every consecutive 8250 I/O instruction. This action will flush the queue and provide 15 clock periods between I/O operations.

Note: This note only applies to programmers using the 8250A directly. It is STRONGLY suggested that the user not communicate directly with the physical hardware, but use the system BIOS instead.

Note: It is important to note that when the IBM PCjr has the Internal Modem installed it is logically COM1 and the RS232 serial port is logically COM2 in BIOS, DOS, and BASIC. Without the Internal Modem installed the RS232 serial port is logically addressed as COM1 in BIOS, DOS, and BASIC even though its address is still hex 2F8 using Interrupt level 3.

The following figure is a Serial Port Block Diagram:

Modes of Operation

The different modes of operation are selected by programming the 8250A asynchronous communications element. This is done by selecting the I/O address (hex 2F8 to 2FF) and 'writing' data out to the card. Address bits A0, A1, and A2 select the different registers that define the modes of operation. Also, the divisor-latch access-bit (bit 7) of the line-control register is used to select certain registers.

I/O Decode (in Hex)	Register Selected	DLAB State
2F8	TX Buffer	DLAB=0 (Write)
2F8	RX Buffer	DLAB=0 (Read)
2F8	Divisor Latch LSB	DLAB=1
2F9	Divisor Latch MSB	DLAB=1
2F9	Interrupt Enable Register	DLAB=0
2FA	Interrupt Identification Registers	(Don't Care)
2FB	Line Control Register	(Don't Care)
2FC	Modem Control Register	(Don't Care)
2FD	Line Status Register	(Don't Care)
2FE	Modem Status Register	(Don't Care)
2FF	Scratch Register	(Don't Care)

I/O Decodes

Address Range hex 2F8 - 2FF

Note: The state of the divisor-latch access-bit (DLAB), which is the most-significant bit of the line-control register, affects the selection of certain 8250A registers. The DLAB must be set 'high' by the system software to access the baud-rate-generator divisor latches.

Interrupts

One interrupt line is provided to the system. This interrupt is IRQ3 and is 'positive active'. To allow the serial port to send interrupts to the system, bit 3 of the modem control register must be set to 1 'high'. At this point, any of the following interrupt types 'enabled' by bits in the interrupt-enable register will cause an interrupt: Receiver-line status, Received Data available, Transmitter-Holding-Register empty, or Modem Status.

Interface Description

The communications adapter provides an EIA RS-232C electrically-compatible interface. One 2 by 8-pin Berg connector is provided to attach to various peripheral devices.

The voltage interface is a serial interface. It supports data and control signals as follows:

Pin A04	Transmit Data
Pin A08	Receive Data
Pin A03	Request to Send
Pin A07	Clear to Send
Pin A06	Data Set Ready
Pin B02-B08	Signal Ground
Pin A05	Carrier Detect
Pin A02	Data Terminal Ready
Pin B01	Shield Ground

The adapter converts these signals to/from TTL levels to EIA voltage levels. These signals are sampled or generated by the communications-control chip. These

signals can then be sensed by the system software to determine the state of the interface or peripheral device.

Note: The above nomenclature describes the communications adapter as a DTE (Data Terminal Equipment) device. Suitable adapters must be used to attach other devices such as serial printers.

Note: Ring Indicate is not supported on the PCjr.

Voltage Interchange Information

Interchange Voltage	Binary State	Signal Condition	Interface Control Function
Positive Voltage =	Binary (0)	= Spacing	= On
Negative Voltage =	Binary (1)	= Marking	= Off

Voltage Interchange Information

+15	Vdo	Invalid Levels
+15	vac	On Function
+3	Vdc	
0	Vdc	Invalid Levels
-3	Vdc	Off Function
-15	Vdc	Invalid Levels

The signal will be considered in the 'marking' condition when the voltage on the interchange circuit, measured at the interface point, is more negative than

-3 Vdc with respect to signal ground. The signal will be considered in the 'spacing' condition when the voltage is more positive than +3 Vdc with respect to signal ground. The region between +3 Vdc and -3 Vdc is defined as the transition region, and considered an invalid level. The voltage which is more negative than -15 Vdc or more positive than +15 Vdc will also be considered an invalid level.

During the transmission of data, the 'marking' condition will be used to denote the binary state 1, and the 'spacing' condition will be used to denote the binary state 0.

For interface control circuits, the function is 'on' when the voltage is more positive than +3 Vdc with respect to signal ground and is 'off' when the voltage is more negative than -3 Vdc with respect to signal ground.

For detailed information regarding the INS8250A Communications Controller, refer to "Bibliography".

Output Signals

Output 1 (OUT 1), Pin 34: Output 1 of the 8250A is not supported in PCjr hardware.

Output 2 (OUT 2), Pin 31: Output 2 of the 8250A is not supported in PCjr hardware.

Accessible Registers

The INS8250A has a number of accessible registers. The system programmer may access or control any of

the INS8250A registers through the processor. These registers are used to control INS8250A operations and to transmit and receive data. For further information regarding accessible registers, refer to "Bibliography".

INS8250A Programmable Baud Rate Generator

The INS8250A contains a programmable baud rate generator that is capable of taking the clock input (1.7895 MHz) and dividing it by any divisor from 1 to (65535). The output frequency of the Baud Rate Generator is 16 x the baud rate [divisor number = (frequency input) / (baud rate x 16)]. Two 8-bit latches store the divisor in a 16-bit binary- format. These divisor latches must be loaded during initialization in order to ensure desired operation of the baud rate generator. Upon loading either of the divisor latches, a 16-bit baud-counter is immediately loaded. This prevents long counts on initial load.

The following figure illustrates the use of the baud rate generator with a frequency of 1.7895 MHz. For baud rates of 4800 and below, the error obtained is minimal.

Note: The maximum operating frequency of the baud generator is 3.1 MHz. In no case should the data rate be greater than 4800 baud.

Desired Baud Rate	Divisor Used to Generate 16x Clock (Decimal) (Hex)		Percent Error Per Bit Difference Between Desired and Actual
50	2237	8BD	.006
75	1491	5D3	.017
110	1017	-1 A 1	.023
134.5	832	167	.054
150	746	12 C	.050
300	373	175	.050
600	186	BA	.218
1200	93	5D	.218
1800	62	3E	.218
2000	56	38	.140
2400	47	2F	.855
3600	31	1 F	.218
4800	23	17	1.291

Baud Rate at 1.7895 MHz

Note: These divisions are different than that used in the IBM Personal Computer. For portability, all initialization should be done through the system BIOS.

Note: Receive rates should not exceed 1200 baud if the receive operation is overlapped with keyboard keystrokes.

The following Assembly language sample program initializes the 8250. The baud rate is set to 1200 baud. It's data word is defined: 8 bits long with 1 stop bit odd parity.

Connector Specifications

System Power Supply

The system power supply is a 33 Watt, three voltage-level, two-stage supply. The first stage is an external power transformer that provides a single-fuse protected, extra low, ac-voltage output. The power cord is 3.08 meters (10.16 feet) long. The second stage is an internal, printed-circuit board, which is vertically mounted into the system board. The second stage converts the transformer's ac-output into three dc-output levels.

The amount of power available on the I/O connector for a machine that is fully configured with internal features is 400 mA of +5 Vdc, 0 mA of +12 Vdc and 0 mA of -6 Vdc.

Power is supplied to the system board through a printed-circuit-board edge-connector. The diskette drive is powered through a separate four-pin connector mounted on the front edge of the Power Board. The power for the diskette drive fan is provided by a three-pin Berg-type connector mounted directly below the diskette-drive connector. Power is removed from the system board and diskette drive by a switch mounted on the rear of the Power Board. Both the switch and the transformer connector are accessible from the rear of the system.

Operating Characteristics

Power Supply Input Requirements

Voltage (Vac)			Frequency	Current (Amps)
Nominal Minimum Maximum		±.5 Hz	Maximum	
120	104	127	60 Hz	.65 at 104 Vac

Voltage ac

IBM PCjr 64KB Memory and Display Expansion

The 64KB Memory and Display Expansion option enables the user to work with the higher density video modes while increasing the system's memory size by 64K bytes to a total of 128K bytes. The memory expansion option plugs into the 44-pin memory expansion connector on the system board. Only one memory expansion is supported.

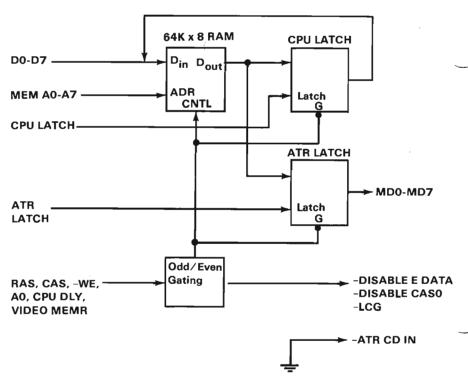

The Memory Expansion Option does not require the user to reconfigure the system to recognize the additional memory.

Eight 64K-by-1, 150 ns, dynamic memory modules provide 64K bytes of storage. The memory modules are Motorola's MCM6665AL15, and Texas Instrument's TMS4164-15, or equivalent.

When inserted, the memory expansion option uses the ODD memory space, while the system memory is decoded as the EVEN memory. Thus, when used as video memory, the memory expansion option has the video attributes while the on-board system memory has the video characters. This arrangement provides a higher bandwidth of video characters.

In addition to the eight memory modules, the expansion card has logic to do the EVEN/ODD address decoding, video data multiplexing, and a CARD PRESENT wrap.

Dynamic-refresh timing and address generation are done on the system board and used by the memory expansion option. The following is a block diagram of the IBM PCjr 64KB Memory and Display Expansion.

Connector Specifications

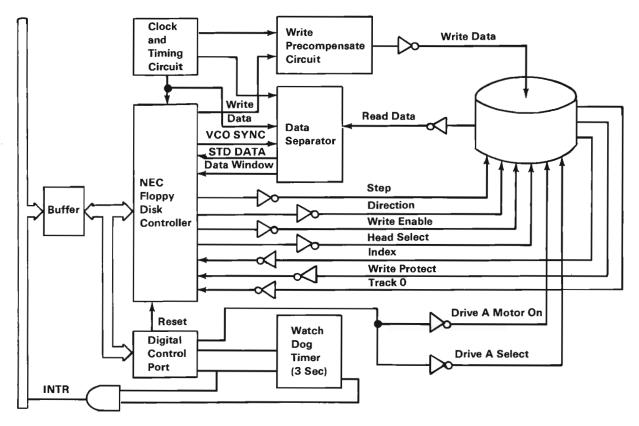

Notes:

IBM PCjr Diskette Drive Adapter

The diskette drive adapter resides in a dedicated connector on the IBM PCjr system board. It is attached to the single diskette drive through a flat, internal, 60-conductor, signal cable.

The general purpose adapter is designed for a double-density, Modified Frequency Modulation (MFM)-coded, diskette drive and uses write precompensation with an analog phase-lock loop for clock and data recovery. The adapter uses the NEC μ PD765 or compatible controller, so the μ PD765 characteristics of the diskette drive can be programmed. In addition, the attachment supports the diskette drive's write-protect feature. The adapter is buffered on the I/O bus and uses the system ROM BIOS for transferring record data. An interrupt level is also used to indicate an error status condition that requires processor attention.

A block diagram of the diskette drive adapter follows.

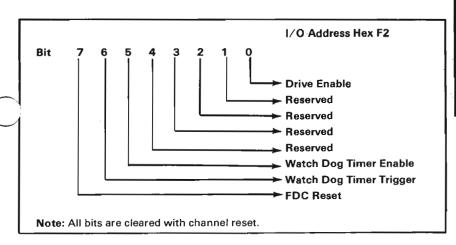

Diskette Drive Adapter Block Diagram.

Functional Description

From a programming point of view, the diskette drive adapter consists of a 4-bit digital output register (DOR) in parallel with a NEC μ PD765 or equivalent floppy disk controller (FDC).

Digital Output Register

The digital output register (DOR) is an output-only register used to control the drive motor and selection. All bits are cleared by the I/O interface reset line. The bits have the following functions:

Digital Output Register

Bit 0 This bit controls the motor and enable lines to the drive. When 'high' (1), this bit will turn 'on' the drive motor and 'enable' the drive. When 'low' (0), this bit will turn 'off' the drive motor and 'disable' the drive.

Bits 1-4 These bits are reserved.

When 'high' (1), this bit 'enables' the WatchDog Timer function and interrupt. When 'low' (0), this bit 'disables' the WatchDog Timer and interrupt.

Bit 6 This bit controls the start of a watchdog timer cycle. Two output commands are required to operate the trigger. A 1 and then a 0 must be written in succession to 'strobe' the trigger.

Bit 7 This bit is the hardware 'reset' for the

Bit 7 This bit is the hardware 'reset' for the floppy diskette controller chip. When 'low' (0), this bit holds the FDC in its 'reset' state. When 'high' (1), this bit releases the 'reset' state on the FDC.

WatchDog Timer

The WatchDog Timer (WDT) is a one to three-second timer connected to interrupt request line 6 (IRQ6) of the 8259. This timer breaks the program out of data transfer loops in the event of a hardware malfunction. The WatchDog Timer starts its cycle when 'triggered.'

Floppy Disk Controller (FDC)

The floppy disk controller (FDC) contains two registers that can be accessed by the system microprocessor: a status register and a data register. The 8-bit main-status register contains the status information of the FDC and can be accessed at any time. The 8-bit data register consists of several registers in a stack with only one register presented to the data bus at a time. The data register stores data, commands, parameters, and provides floppy disk drive (FDD) status information. Data bytes are read from or written to the data register in order to program or obtain results after

a particular command. The main status register can only be read and is used to facilitate the transfer of data between the system microprocessor and FDC.

FDC Register I/O Address
Data Register hex F5
Main Status Register hex F4

Programming Summary

The FDC is set up with the following Parameters during system power up:

	Parameter	Power-up Condition
ſ	Sector Size	hex 02 for 512 Byte Sectors
	Sector Count	9
;	Head Unload	hex 0F - Has no effect on system operation.
	Head Step Rate	hex D - This gives a step rate of 6 milliseconds.
	Head Load Time	hex 1 Minimum head load time.
	Format Gap	hex 50
	Write Gap	hex 2A
	Non-DMA Mode	hex 1
	Fill byte for Format	hex F6

FDC Power-up Parameters Settings

The IBM PCjr Diskette Drive Adapter and BIOS use and support the following FDC commands:

- Specify
- Recalibrate
- Seek
- Sense interrupt status
- Sense Drive status
- Read data
- Write data
- Format a track

Note: Please refer to the Diskette section of the BIOS listing for details of how these commands are used.

The following FDC hardware functions are not implemented or supported by the IBM PCjr Diskette Drive Adapter.

- DMA data transfer
- FDC interrupt
- Drive polling and overlapped seek
- · FM data incoding
- · Unit select status bits

2 Heads (1 per side)

40 Cylinders (Tracks)/Side

9 Sectors/Track

512 Bytes/Sector

Modified Frequency Modulation (MFM)

Diskette Format

Constant	Value	
Head Load	Not Applicable	
Head Settle	21 Milliseconds	
Motor Start	500 Milliseconds	

Drive Constants

Comments

- 1. Head loads when diskette is clamped.
- Following access, wait Head Settle time before RD/WR.
- Drive motor should be 'off' when not in use. Wait Motor Start time before RD/WR.
- All system interrupts except IRQ6 must be 'disabled' during diskette data transfer in order to prevent data under-run or over-run conditions from occurring.

System I/O Channel Interface

All signals are TTL-compatible:

Most-Positive Up-Level	+ 5.5 Vdc
Least-Positive Up-Level	+ 2.7 Vdc
Most-Positive Down-Level	+ 0.5 Vdc
Least-Positive Down-Level	- 0.5 Vdc

The following lines are used by this adapter:

+D0 thru 7 (Bidirectional, Load: 1 74LS,

Driver: 74LS 3-state)

These eight lines form a bus through which all commands, status, and data are transferred. Bit 0 is the low-order bit.

(Adapter Input, Load: 174LS) +A0 thru 3

> These four lines form an address bus by which a register is selected to receive or supply the byte transferred through lines D0-7. Bit 0

is the low-order bit.

(Adapter Input, Load: 1 74LS)

The content of lines D0-7 is stored in the register addressed by lines A0-3 at the trailing edge of this

signal.

(Adapter Input, Load: 174LS) -IOR

> The content of the register addressed by lines A0-3 is 'gated' onto lines D0-7 when this line is 'active.'

(Adapter Input, Load: 174LS)

A down level 'aborts' any operation in process and 'clears' the digital output register (DOR).

(Adapter Output, Driver: 74LS

3-state)

This line is made 'active' when the WatchDog timer times out.

(Adapter Output, Driver: Gnd.)

This line is pulled 'up' on the System Board and is wired to input port bit PC2 on port hex 62 of the

-IOW

-RESET

+IRQ6

-DISKETTE CARD INSTALLED 8255. This line is used by the program to determine if the diskette drive adapter is installed.

-Diskette CS (Adapter Input, Load: 174LS)

765)

This line is shared with the modem CS line and is 'low' whenever the microprocessor is doing IOR or IOW to either the diskette adapter or the modem. This line should be conditioned with A9 being 'low' to generate a DISKETTE CS.

(Adapter Input, Load: 174LS)

This line is the microprocessor address line 9. When this line is 'low' and -DISKETTE CS is 'low' IOR and IOW are used by the diskette adapter. (adapter Output, Driver: NEC μpd

This output would indicate to a DMA device on the external I/O Channel that the diskette controller wants to 'receive' or 'transmit' a byte of data to or from memory. (Adapter input, Load: NEC μpd 765)

This line should come from an external DMA and should indicate that a byte is being transferred from/to the Floppy Disk Controller to/from memory.

A9

DRQ 0

DACK 0

Drive Interface

All signals are TTL-compatible:

Most Positive Up Level	+ 5.5 Vdc
Least Positive Up Level	+ 2.4 Vdc
Most Positive Down Level	+ 0.4 Vdc
Least Positive Down Level	- 0.5 Vdc

All adapter outputs are driven by active collector gates. The drive should not provide termination networks to Vcc (except Drive Select which has a 2,000 ohm resistor to Vcc).

Each attachment input is terminated with a 2,000 ohm resistor to Vcc.

Adapter Outputs

-Drive Select	(Driver: MC3487)
-Motor Enable	This line is used to 'degate' all drivers to the adapter and receivers from the adapter (except Motor Enable) when the line is not 'active.' (Driver: 74LS04)
-Step	The drive must control its spindle motor to 'start' when the line becomes 'active' and 'stop' when the line becomes 'inactive.' (Driver: MC3487)
	The selected drive must move the read/write head one cylinder in or

out as instructed by the Direction line for each pulse present on this line.

-Direction

(Driver: MC3487)

For each recognized pulse of the step line the read/write head should move one cylinder toward the spindle if this line is active, and away from the spindle if not-active.

-Write Data

(Driver: 74LS04)

For each 'inactive' to 'active' transition of this line while Write Enable is 'active', the selected drive must cause a flux change to be stored on the diskette.

-Write Enable

(Driver: MC3487)

The drive must 'disable' write current in the head unless this line is 'active.'

-HEAD SELECT 1

(Driver: MC3487)

This interface signal defines which side of a two-sided diskette is used for data recording or retrieval. A 'high' level on this line selects the R/W head on the side 1 surface of the diskette. When switching from side 0 to side 1 and conversely, a $100 \mu s$ delay is required before any 'read' or 'write' operation can be initiated.

Adapter Inputs

-Index The selected drive must supply

one pulse per diskette

revolution on this line.

-Write Protect The selected drive must make

this line 'active' if a write-protected diskette is

mounted in the drive.

-Track 0 The selected drive must make

this line 'active' if the

read/write head is over track

0.

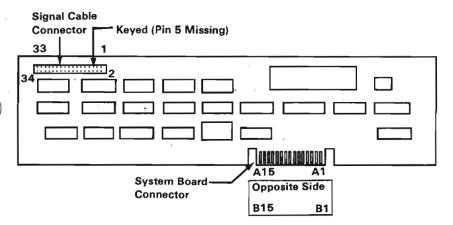

-Read Data The selected drive must supply

a pulse on this line for each flux change encountered on the

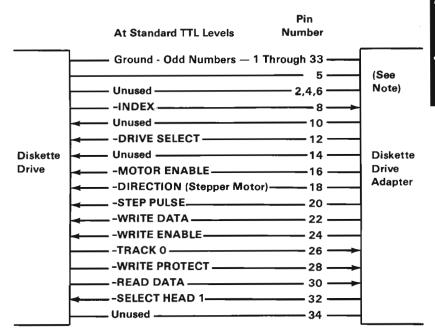

diskette.

Voltage and Current Requirements

The diskette drive adapter requires a voltage supply of +5 Vdc +/- 5% and draws a nominal current of 525 mA and a maximum current of 700 mA.

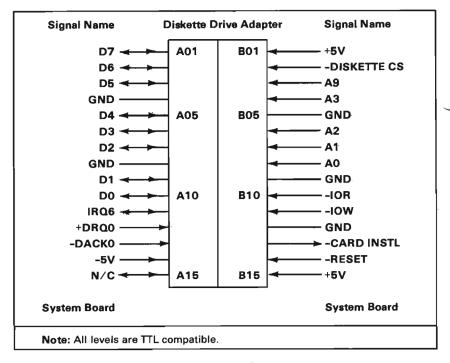

Diskette Drive Adapter

Note: Pin 5 is missing to match the key plug on the signal cable.

Connector Specifications (Part 1 of 2)

Connector Specifications (Part 2 of 2)

IBM PCjr Diskette Drive

The system unit has space and power for one diskette drive. The drive is double-sided with 40 tracks for each side, is fully self-contained, and consists of a spindle-drive system, a read-positioning system, and a read/write/erase system.

Functional Description

The diskette drive uses modified frequency modulation (MFM) to read and write digital-data, with a track-to-track access time of 6 milliseconds.

To load a diskette, the operator rotates the load lever at the front of the diskette drive clockwise and inserts the diskette into the slot. Plastic guides in the slot ensure the diskette is in the correct position. Closing the load lever centers the diskette and clamps it to the drive hub. This same action also loads the Read/Write heads against the surfaces of the diskette. The load lever is mechanically interlocked to prevent closing of the lever if a diskette is not installed.

The head-positioning system moves the magnetic head to come in contact with the desired track of the diskette. Operator intervention is not required during normal operation. If the diskette is write-protected, a write-protect sensor 'disables' the drive's circuitry, and an appropriate signal is sent to the interface.

Data is read from the diskette by the data-recovery circuitry, which consists of a low-level read-amplifier, differentiator, zero-crossing detector, and digitizing circuits. All data decoding is done by the adapter card.

The IBM PCjr Diskette Drive is equipped with a media cooling fan, which gets its power from the power supply board.

The diskette drive also has the following sensor systems:

- The track 00 sensor, senses when the head/carriage assembly is at track 00.
- The index sensor, which consists of an LED light source and phototransistor. This sensor is positioned so that when an index hole is detected, a digital signal is generated.
- The write-protect sensor 'disables' the diskette drive's electronics whenever it senses a write-protect tab on the diskette.

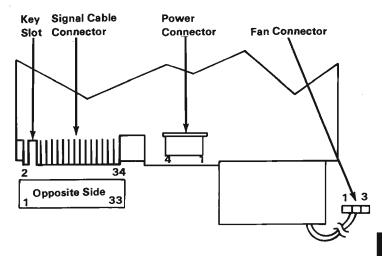

The drive requires power within the following specifications:

Specification	+5 Vdc Input	+12 Vdc Input
Nominal Supply Ripple (0 to 50 kHz) Tolerance (Including Ripple) Standby Current (Nominal) Standby Current (Worst Case) Operating Current (Nominal) Operating Current (Worst Case)	+5 Vdc 100 mV ±5% 600 mA 700 mA 600 mA 700 mA	+12 Vdc 100 mV ±5% 400 mA 500 mA 900 mA 2400 mA

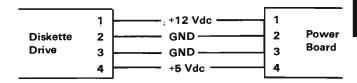

Diskette Drive Power Specifications

For interface information refer to "Diskette Drive Adapter" in this section.

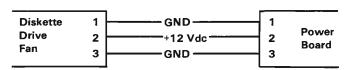

For mechanical and electrical specifications see Appendix D.

Diskette Drive Connectors

Connector Specifications (Part 1 of 2)

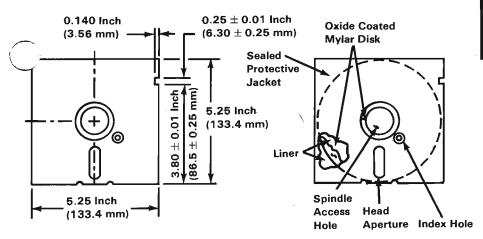

Connector Specifications (Part 2 of 2)

Notes:

Diskette

The IBM PCjr Diskette Drive uses a standard 133.4 mm (5.25 in.) diskette. For programming considerations, single-sided, double-density, soft-sectored diskettes are used for single-sided drives. Double-sided drives use double-sided, double-density, soft-sectored diskettes. The figure below is a simplified drawing of the diskette used with the diskette drive. This recording medium is a flexible magnetic disk enclosed in a protective jacket. The protected disk, free to rotate within the jacket, is continuously cleaned by the soft fabric lining of the jacket during normal operation. Read/write/erase head access is through an opening in the jacket. Openings for the drive hub and diskette index hole are also provided.

Recording Medium

Notes:

IBM PCjr Internal Modem

The IBM PCjr Internal Modem is a 65 mm (2.5 inch) by 190 mm (7.5 inch) adapter that plugs into the PCjr system board modem connector. The modem connector is an extension of the system I/O bus. All system control signals and voltage requirements are provided through a 2 by 15 position card-edge tab with 0.254 cm (0.100-inch) spacing on the modem adapter.

Functional Description

The Internal Modem consists of two major parts: (1) the INS8250A Asynchronous Communication Element, and (2) the Smart 103 Modem. Therefore, the programming must be considered in two parts. The INS8250A communications protocol is a function of the system ROM BIOS, and is discussed later in this section. All 'pacing' of the interface and control-signal status must be handled by the system software. After the INS8250A is initialized, the modem is controlled by ASCII characters transmitted by the INS8250A.

Key features of the INS8250A used in the modem adapter are:

- Adds or deletes start bits, stop bits, and parity bits to or from the serial data stream
- Full double-buffering eliminates the need for precise synchronization
- Independently-controlled transmit, receive, line status, and data-set interrupts
- Programmable baud-rate-generator allows division of the baud clock by 373 (hex 175) for a 300-bps transmission-speed or 1017 (hex 3F9) for a 110-bps transmission-speed to generate the internal 16 x clock

- Modem-control functions: Clear to Send (CTS), Data Set Ready (DSR), Data Terminal Ready (DTR), Ring Indicator (RI), and Data Carrier Detect (DCD)
- Fully-programmable serial-interface

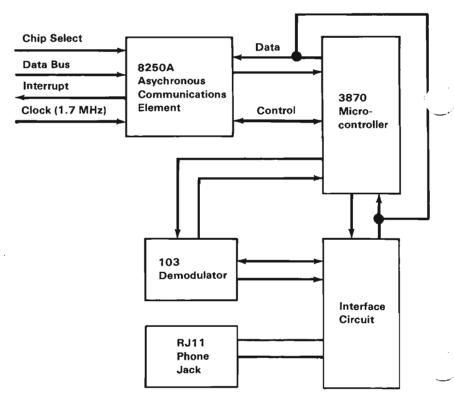

characteristics:

- 7, or 8-bit characters
- Even, odd, or no-parity bit generation and detection
- 1 stop-bit generation
- Baud-rate generation
- False-start bit detection
- Complete status reporting capabilities
- · Line-break generation and detection
- · Internal-diagnostic capabilities
 - Loopback controls for communications-link fault-isolation
 - Break, parity, overrun, framing-error simulation
- Fully prioritized-interrupt system-controls

Key features of the Smart 103 Modem used on the IBM PCjr Internal Modem are:

- Direct connection to a telephone company line through an FCC Part-68-approved permissive connection
- Compatible to Bell Series 100 originate/answer for modulation and handshaking
- All functions controlled by ASCII characters and INS8250A modem-control lines
- Uses modular phone-jack (USOC RJ11)
- Data rate is either 300 or 110 bits-per-second
- Auto/manual originate
- Auto/manual answer
- Communication mode is full duplex on two-wire, switched-network channels

- Auto dialer; either DTMF ([dual-tone modulated-frequency] touch-tone) or pulse-dialing (rotary dial) by software command
- · Tandem dialing
- · Call-progress reporting
- Dial-tone, ring-back tone, and busy-tone detection

IBM PCjr Internal Modem Block Diagram

Modem Design Parameters

The following tables describe the design parameters of the Smart 103 Modem.

\ j	Dialer Type:	Two modes 1. Forced Touch-Tone (DTMF) dialing 2. Forced pulse dialing
	Tandem Dialing:	The ASCII character P (hex 50 or 70) in the dial string causes a delay of up to 10 seconds while the modem is searching for another dial tone. A time out will cause the modem to hang up and post status. The ASCII character W (hex 57 or 77) in the dial string causes a 5-second dead wait before continuing to dial. Multiple ASCII W's will cause multiple waits.
$\Big $	Pulse Dialing:	Rate: 10 + 1, -0 pulses per second Duty Cycle: 60% make, 40% break Interdigit Delay: 800 ms ± 50 ms
	DTMF Dialing:	Tone Duration: 85 ms \pm 10 ms Intertone Duration: 80 ms \pm 10 ms

Transmitter/Receiver Frequency Parameters

Pagaiya Sangitiyity	More negative or equal to -42 dBm.
Receive Sensitivity	Whole negative of equal to -42 dbm.

Receive Sensitivity Parameters

Fixed at -10 dBm as per FCC Part 68 Permissive connection.

Transmitter Level Parameter

Programming Considerations

The modem and the IBM PCjr system can communicate commands or data between each other. Any commands sent to the modem from the IBM PCjr are stripped from the data stream and executed but are not transmitted to the receiving station. The data is transparent to the modem. The modem is capable of causing hardware interrupts as the result of certain conditions, and in response to queries for its status.

Commands to the modem are a sequence of characters preceded by a single command character. The command character tells the modem that the following character sequence, until a carriage return, is a command. The carriage return completes the command sequence and causes the modem to execute the commands. The command character (represented by [cc] in the following text) is programmable (with the NEW command) to any ASCII character (hex 00 thru 7F). The default for the command character is Ctrl N (ASCII hex 0E).

Commands can occur anywhere in the data stream if properly formatted but are not to be executed by the modem until a carriage return is received.

Multiple commands are allowed if separated by commas and preceded by a single command character.

Command Format

The following is the command format that all commands must follow.

[cc][command word][delimiter][arguments] [,more][CR]

where:

[cc] is the single ASCII command

character.

[command word] is the command word or the first

letter of the command word.

[delimiter] is always a space when separating

an argument and command word. Any spaces thereafter are ignored until the modem sees a comma, an

argument or a carriage return.

[arguments] is a variable that is replaced by any

character allowed by the command

definition.

[,more] is any additional commands

preceded by a comma.

[CR] is a carriage return that completes

the command sequence and causes

the modem to execute the

commands.

The following are two examples of command format.

[cc] COUNT 5 [CR] sample test [cc] VOICE, D (408) 555-1234,QUERY [CR]

Format Guidelines

- 1. Commands can occur anywhere in the data stream if properly formatted but are not be executed by the modem until a carriage return is received.
- Multiple commands are allowed if separated by commas and preceded by a single command-character.
- 3. Only the first character of the command word is significant. All remaining characters are ignored up to the first space following the command word. In other words, the **DIAL** command and **DUMMY** are treated identically.

- 4. The modem does not discriminate between upper-case and lower-case characters.
- 5. There are three ways to send the current command-character as data to a receiving station:
 - a. Consecutively sending it twice:

[cc][cc]

This would send the character a single time.

- b. Change the command character (with the **NEW** command) to another ASCII character and then transmit the previous command-character.
- c. Place the modem in the Transparent mode and then transmit the character.

Commands

The commands that are used with the integrated modem are listed on the following pages in alphabetical order.

Each of the commands has its syntax described according to the following conventions:

- 1. Words in capital letters are keywords. Only the first letter of the keyword is required, the others are optional.
- 2. You must supply any arguments which are in lower-case letters. Valid characters for arguments are defined as:
 - m ASCII decimal digits 0 to 9, *, #, I, P, and W
 - n ASCII hexadecimal digits 0 to F
 - o ASCII hexadecimal digits 0 to 9
 - p any ASCII character

- All arguments are examined for validity. If extra characters are used in an argument, the extra characters are ignored. If the argument is invalid, the command is ignored.
- 4. An ellipsis (...) indicates an item may be repeated as many times as you wish.
- 5. All command lines must begin with a command character. The default command-character is (CONTROL N).
- 6. Multiple commands separated by commas can follow a single command-character.

An example of the DIAL command is given below:

Command format - DIAL m...m

Command line - DIAL 1 800 555 1234

If an invalid argument or no argument is given, the command is not executed. Also, a question mark (?) is given as the error response and the command line is aborted.

The commands are as follows:

Format: ANSWER

A

Purpose: To logically take the phone off the hook and force

ANSWER mode. This is logically like a manual

answer.

Format: Break n

Purpose: To send a space or break character for a duration

equal to a multiple of 100 ms (n x 100 ms).

Format: COUNT n

C_n

Where **n** is the number of complete rings in the range of hex 0 to hex F.

When answering an incoming call, the modem answers the phone after n complete incoming rings, where n is any value from hex 0 to F.

A value of zero specifies that the modem not answer an incoming call, but still carry out any instructions from the host.

When dialing, the modem waits n + 3 complete ringbacks before cancelling the call.

If n exceeds 4, the 45-second abort timer cancels an outgoing call with an "UNSUCCESSFUL" response, as more than seven ringbacks exceeds 45 seconds.

Purpose: Sets the ring count when the modem is answering an

incoming call or dialing a call.

Default: 0

Format: DIAL m...m

D m...m

Where m...m is a dial string of ASCII decimal digits 0 through 9, *, #, I, P, and W. A maximum of 33 characters are allowed in the dial string. The first character of the string defaults to P (a 10-second delay while searching for the dial tone). W causes the modem to delay five seconds, then continue dialing.

W or P must start a string, can also occur anywhere within a string, and causes the digits to be tone dialed.

The characters * and # represent the two extra buttons on a push-button phone, but may be used for other things.

I causes the next digits to be pulse dialed. The I stays in effect until a (P,), (W,), or end of command. The modem then searches for line busy, ringing, or incoming carriers while posting the status.

Purpose: To cause the modem to dial.

Default: P (10-second timeout). (If this command is used without an argument, the last number dialed is redialed once.)

Format: FORMAT n

Fn

Where n is one of the following:

n	Parity	Data Length	Stop Bit
0	Mark	7	1
1	Space	7	1
2	Odd	7	1
3	Even	7	1
4	None	8	1
5-7	Reserved		

The 8250A line control register (LCR) must specify the same format as defined in the FORMAT n command to 'enable' data/command communication.

Do not combine this command with any other commands except the **SPEED** command on a single command line.

Note: If programming in BASIC, this command must be used in addition to specifying the same parity and data length in the BASIC 'open' statement.

Purpose:

To change the parity and number of stop-bits being transmitted at either end, to a new format.

Default:

3

Format: HANGUP

H

Purpose: To perform a clean disconnect and go on-hook.

Logically the same as manually hanging up.

Format: INITIALIZE

I

This command is executed in 10 seconds and is the same as a cold start. An "OK" response is not returned after execution and the integrity test code in

the QUERY command is set.

Purpose: Places the modem in the power-up default-state.

Format: LONG RESPONSE o

L o

Where o is one of the following:

0	Mode	Responses
0	Verbose	
		"BUSY"
		"CONNECTED"
		"NO ANSWER"
		"NO DIAL TONE"
		"OK"
		"RING"
		"UNSUCCESSFUL"
		"?" (Question
	,	Mark)
1	Terse (Hex code)	
		30
		31
		32
		33
		34
		35
		36
		37

Note: The dial string is not echoed in the terse mode.

Purpose: Modifies message feedback. Information is posted in

the status area.

Default: 0 (Verbose mode)

Format: MODEM

M

Purpose: Forces the modem into the data state where the

carrier is placed on the telephone line and proper

connection-protocols are followed.

This command is equivalent to ANSWER if the data

state started as autoanswer.

Format: NEW p

Νp

where p is any ASCII character.(hex 0E)

Purpose: Changes the command character to an ASCII

character.

Default: Ctrl N (ASCII hex 0E)

Format: ORIGINATE

 \mathbf{o}

Purpose: Logically takes the phone off-hook and forces the

ORIGINATE mode. Logically equivalent to manual

originate.

Format: PICKUP

P

Purpose: Logically takes the phone off-hook and puts the

modem in the voice state.

Format: QUERY

Q

Purpose: To query the modem for its status information.

Possible characters returned by the modem are as follows:

Responses	Meaning
H0 or H1	Hook status: H0 = on-hook, H1 = off-hook.
S0 to SF	Current ringcount setting in hex.
B	I ina busy
D	Line busy. Line dead: no dial-tone found or no
D	ring/no busy timeout after dialing.
L	Successful dial and handshake.
N	Dial not recorded: dial tone present after dialing.
X	No answer: ringcount plus 3 exceeded.
T0	Integrity test passed.
T1	Integrity test failed.

The first group of characters is always returned for a QUERY command. The second group of characters is returned only after a dialing sequence has been started or a change has occurred in the dialing status. The third group of characters is returned when a TEST command has occurred. All characters except the first group are erased by being read and do not appear in response to the next QUERY unless the

condition has recurred in the interim. The **QUERY** response overrides any incoming data from the telephone line.

Format: RETRY

R

Purpose: When placed after a DIAL command, it causes the

modem to execute up to 10 redials at a rate of one per 40 seconds. The redials are triggered by a busy

detection after dialing.

Format: SPEED o

So

Where o is one of the following:

o bps

0 - 110

1 - 300

2 - Reserved

Note: Do not combine this command with other commands except the **FORMAT** command on a single command line.

The **SPEED** command must be issued before the 8250A baud rate is changed.

Note: If programming in BASIC, this command must be used in addition to specifying the same bps rate in the BASIC 'open' statement.

Purpose: Sets the baud rate.

Default: 1 (300 bps)

Format: TRANSPARENT n...n

T n...n

Where n...n is the number of bytes to transmit in the range of hex 0 to hex FFFF.

Purpose:

Places the modem in the transparent mode for the next n...n bytes.

The modem does not look for command sequences but instead transmits every character it receives.

The argument can be up to four ASCII-coded hex digits long. This provides a range of 65,536 bytes.

If an argument is not included with the TRANSPARENT command, the command is ignored because it has no default.

The transparent mode is terminated when:

- 1. n...n characters have been transmitted.
- 2. Loss of carrier timeout.
- 3. INS8250A OUT 1 pin goes 'active.' (The INS8250A -OUT 1 signal should remain 'active' until the transparent mode is requested again.)

The modem exits the transparent mode before processing the next complete character from the host.

To re-enter the transparent mode, the sequence is:

- 1. The INS8250A -OUT 1 pin changes to, or remains in the 'inactive' state.
- 2. The command string containing the TRANSPARENT command is issued.

An argument of 0 causes a permanent transparent mode which can be exited by the INS8250A -OUT 1 pin going 'active.'

Format: VOICE

 \mathbf{V}

Purpose:

Forces the modem to the voice state where no tones or carriers are placed or searched for on the telephone line.

This state is used for voice communication, when the modem is an autodialer or answering device only. It is also necessary to be in the voice state to transmit DTMF tone-pairs.

This command 'disables' the autoanswer function.

The status responses are:

- 1. If a busy signal is detected "BUSY OK".
- 2. Any other condition "OK...(16 dots)....CONNECTED".

Format: WAIT

W

Purpose: Causes the modem to take no action, including

autoanswer, until the next command is received from

the host. All commands following the WAIT command in a single command-line are ignored.

Format: XMIT m...m

X m...m

Purpose: Instructs the modem to transmit the DTMF

tone-pairs found in the argument string m...m. This is only valid in the voice state. Delays between digits

can be caused by inserting W's in the string.

Each W causes a five-second delay.

Format: ZTEST o

Z o

Where o is one of the following:

o Test

0 - Hardware Integrity Test

1 - Analog Loop Back Test

Purpose: Places the modem in the test mode specified by the argument.

For modes other than the integrity test, the modem stays in the test mode until any other command is received.

For the integrity test, the test is performed, status posted, and then the modem returns to service immediately. The integrity test takes eight to 10 seconds to execute and its completion is signaled by an "OK" message.

All commands following the ZTEST command in a single command-line are ignored.

Responses

Autoanswer

If -DTR is 'active', the modem goes off-hook and proper connection protocols including the two-second billing delay are followed. If connection is made, the modem sends "CONNECTED" to the host and posts the status in the status area.

Editing/Changing Command Lines

Corrections to the command line can be performed by aborting current-command lines and typing a new line or by entering the correct command later on in the current-command line.

The last command entered on a single command-line supersedes any previously entered command that performs an opposite function.

A Control X or backspace received by the modem immediately aborts the entire command line.

Opposite Commands

The command line is scanned after its completion (after [CR] is entered). Commands which cause an action during the scan (for example, DIAL) are not candidates for opposite treatment. Only commands which 'preset' a static condition can be opposites.

They include:

Count (n)	two entries, latest are used
Format (n)	two entries, latest are used
New (p)	two entries, latest are used
Speed (n)	two entries, latest are used
Transparent nn	two entries, latest are used
Modem - Voice	these are opposites only when
	on-hook

Note: Answer and originate are not opposites; each of these causes an action when scanned.

Status Conditions

The modem sends the host messages as defined in the LONG RESPONSE command for dialing success or failure. Hardware interrupts for carrier loss and detecting incoming rings are provided on the 8250A.

Dialing and Loss of Carrier

The dialing process begins with the modem searching for a dial tone if it is not in the blind dialing mode. If a dial tone is not detected, the modem hangs up, the appropriate status characters are posted, and the "NO DIAL TONE" message is returned to the host.

If a dial tone is found, the modem continues to dial. When a P is encountered in the dial string, the modem delays for up to 10 seconds to search for another dial tone and returns the "NO DIAL TONE" message to the host if a dial tone is not detected. When a W is encountered in the dial string, the modem delays for five seconds before continuing to dial. Consecutive W's are allowed in a dial string.

Anytime a P or W is not followed with an I in a dial string, the next digits are tone-dialed. When an I follows a P or W, all following digits are pulse-dialed until a P, W, or end of command ([CR]) is detected.

The modem ignores any character except 0 through 9, *, #, I, P, or W while dialing. This allows the user to place parentheses and dashes in the dial string for greater legibility.

The modem checks the telephone line again after it has dialed the digits in the dial string. If a dial tone is found immediately, the dialed digits are not recorded and the modem posts this to the status characters, hangs up, and sends the "UNSUCCESSFUL" message to the host. If the line is busy, this is also posted to the status characters and the modem hangs up and returns the "BUSY" message to the host. If the line is ringing, the modem begins counting the number of rings. If this count exceeds the value of COUNT + 3, the modem hangs up and takes the same actions as above. If no answer tone is detected within 45 seconds after completion of dialing, the modem hangs up and takes the same actions as above.

Finally, if the call is answered, the modem either looks for a carrier and begins the handshake sequence (if it is in the data or modem state) or remains silent (if it is in the voice state). In the voice state, the modem looks for busy, and transmits a response (1) when the line is found not busy, or (2) if it is found busy, in which case it also hangs up and possibly dials again. In voice state, ringback count and abort time out are not used.

If, during the process of establishing the data link after dialing, the modem receives any character from the host or - DTR goes 'inactive', the modem aborts the call with a clean disconnect, clears the balance of the command line, and sends an "OK" message. Also, the modem does not carry out the instruction sent from the host, even if the character is a command character.

In the data state, the modem transmits a message after successful completion of the handshake, or after it has determined that the handshake failed. An unsuccessful handshake is evidenced by absence of carrier at the proper time.

If a carrier drops out for more than two seconds in the data state, the modem begins a timeout lasting approximately 17 seconds. At the end of the timeout, the modem hangs up. Any command received during the 17 seconds resets the timer.

The modem does not automatically reestablish the connection if the carrier returns after this dropout interval. This allows the user or software to intercede by commanding the modem to go into the voice state, to hang up immediately, or to take some other action. The data connection may also be terminated by a HANGUP command while carriers are still present. A voice connection is always terminated by a HANGUP command.

Default State

Upon power up or after an **INITIALIZE** command is given, the modem returns to the default state as follows:

- A verification of hardware integrity is performed and the result posted to the status characters.
- · The remaining status characters cleared.
- The modem is placed in the data state awaiting a dialing request or incoming ring.
- The Transparent mode is cleared.
- All loopback modes are cleared.
- The wait mode is cleared.
- The command character is set to Control-N.
- The data format is set to 7 data bits, even parity, and one stop bit.
- Ringcount is set to 0 (auto answer 'disabled')
- The modem is set to on-hook.
- The message mode is set to verbose.

Programming Examples

Call progress reporting is done in two modes, verbose messages or terse messages as defined in LONG RESPONSE command to the Serial In (SIN) pin of the 8250A. The power-up default is the verbose messages mode, and these messages from the modem are in capital letters. Also, in call progress reporting, the status area is updated.

The following examples are representative of real-time call-progress reporting. The italicized entries are user entries.

Example 1:

OK [cc]Dial 555-1234 [CR] NO DIAL TONE OK

In this example, no dial tone is detected within the time out period.

Example 2:

OK [cc]Dial 555-1234 [CR]

5551234.....

RINGCONNECTED OK

In this example, a modem answer tone is detected.

Example 3:

OK [cc]Dial 1(301)555-1234 [CR] 13015551234..... BUSY OK

In this example, busy is detected.

Example 4:
OK
[cc]Dial 555-1234 [CR]
5551234
RING
RING
RINGNO ANSWER
OK

In this example, ring count is exceeded before ringing stops.

Example 5: OK [cc]Dial 555-1234 [CR] 5551234...... RING...... UNSUCCESSFUL

OK

In this example, a failed-call time-out occurred because an answer tone was not detected within the allotted time.

Example 6:

OK [cc]Dial 99P555-1234 [CR] 99......NO DIAL TONE OK

In this example, the second dial-tone is not detected within the time out period.

Example 7:

OK [cc]Dial 99P421-7229 [CR] 99.....BUSY OK

In this example, busy is detected within the time-out period.

Example 8:	
OK	
[cc]Dial 99WW555-1234 [CR]	
	••••••
	•••••
•••••	

4217229....
RING......CONNECTED OK

In this example, the access code is dialed and two dead waits are performed. Then, the second number is dialed and a modem answers.

Example 9:

OK

[cc]Dial 555-1234, Retry [CR] 5551234.....BUSY 5551234.....BUSY 5551234.....CONNECTED OK

In this example, the modem dials a number with auto redial. The first two times, the number is busy. The third time, a modem answers.

Modes of Operation

The different modes of operation are selected by programming the 8250A Asynchronous Communication Element. This is done by selecting the I/O address (hex 3F8 to 3FF) and writing data out to the card.

The 8250A is externally programmed to provide asynchronous, ASCII, 10 bit character length including start, stop, and parity on the serial-output pin (SOUT, pin 11). The data rate is 110 or 300 bits-per-second. The commands can be either upper-case or lower-case characters. See the command, Format [n], earlier in this section for additional information.

For further information refer to "Bibliography."

Hex		Input/	Mode		
Address	Register Selected	Output	1	2	Notes
3F8	Transmit Buffer	Write	XX	XX	*
3F8	Receive Buffer	Read	XX	XX	*
3F8	Divisor Latch LSB	Write	75	F9	**
3F9	Divisor Latch MSB	Write	01	03	**
3F9	Interrupt Enable	Write	0F	0F	*
3FA	Interrupt	Read	XX	XX	
	Identification				
3FB	Line Control	Write	1A	03	
3FC	Modem Control	Write	10	01	
3FD	Line Status	Read	XX	XX	
3FE	Modem Status	Read	XX	XX	
3FF	Scratch Pad	Write	XX	XX	

^{*}DLAB = 0 (Bit 7 in line control Register).

8250A Register Description

^{**}DLAB = 1 (Bit 7 in line control Register).

Mode 1 - 300 BPS - 7 Data Bits, 1 Stop Bit, Even Parity.

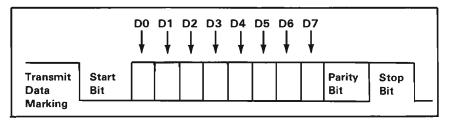

Mode 2 - 110 BPS - 8 Data Bits, 1 Stop Bit, No Parity.

Interrupts

One interrupt line is provided to the system. This interrupt is IRQ4 and is 'positive active.' The interrupt enable register must be properly programmed to allow interrupts.

Data Format

The data format is as follows:

Transmitter Output and Receiver Input Data Format

Data bit 0 is the first bit to be transmitted or received. The attachment automatically inserts the start bit, the correct parity-bit if programmed to do so, and the stop bit.

Interfaces

8250A to Modem Interface

The following describes the 8250A to 103 modem interface:

Signal

Description

3-70 Internal Modem

INS8250A -OUT 1	The 'inactive' state enables entry into the transparent mode using the UNLISTEN command. The 'active' state 'disables' the transparent mode.
-OUT 2	No connection

connection.

SOUT

Serial output from the 8250A.

-RTS

-Request To Send

No connection.

-DTR

-Data Terminal Ready

- 1. To accept a command, -DTR must be 'active.'
- 2. If -DTR goes 'inactive'. the modem does a clean disconnect sequence.
- 3. In auto-answer mode, the modem does not go off-hook, but RI on the 8250A will be toggled if the ringing signal is present.

SIN

Serial input to the 8250A.

-RI

The ring indicator pulses with an incoming ring voltage.

-CTS

-Clear To Send

This line is wired 'active' on the modem adapter.

-DSR

-Data Set Ready

This line is wired 'active' on the modem adapter.

-RLSD

-Received Line Signal Detect

When 'low', this line indicates the data carrier has been detected. If the carrier drops out for longer than two seconds, this line goes 'inactive' and starts the timeout timer.

-RESET, +XRESET

These lines are used to reset or initialize the modem logic upon power-up. These lines are synchronized to the falling edge of the clock. Its duration upon power up is 26.5 ms -RESET is 'active low'. +XRESET is 'active high.'

A0,A1,A2,A9

Address bits 0 to 3 and bit 9. These bits are used with -MODEM CS to select a register on the modem card.

-MODEM CS DISKETTE CS This line is 'active' for addresses hex 0F0 thru 0FF and 3F8 thru 3FF. It is gated with A9 in the 8250A to exclusively decode hex 3F8 thru 3FF.

D0 thru D7 Data bits 0 thru 7:

These eight lines form a bus through which all data is transferred. Bit 0 is the least significant bit (LSB).

-IOR

The content of the register addresses by line A0 thru A2 is gated onto lines D0 thru D7 when this line is 'active', -MODEM CS is 'active', and A9 is 'high.'

-IOW

The content of lines D0 thru S7 is stored in the register addressed by A0 thru A2 at the leading edge of this signal when -MODEM CS is 'active', and A9 is 'high.'

BAUDCLK

This is a 1.7895 MHz clock signal used to drive the Baud Rate Generator.

+MODEM INTR

This line is connected to the +IQRP4 on the 8259A Interrupt Controller.

-CARD INSTALL

This line indicates to the system BIOS that an IBM PCjr Internal Modem is installed in the feature location.

Telephone Company Interface

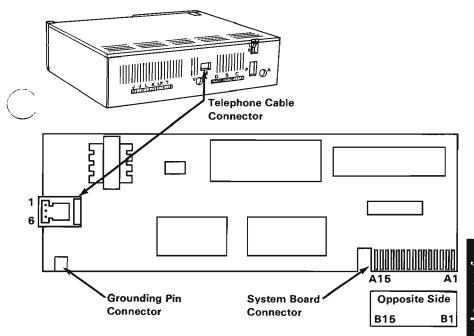

The telephone company interface is a 600 Ohm, balanced, two-wire telephone-interface design that meets the FCC Part 68 rules. A 2.13 meter (7 foot) modular telephone cord is included with the modem adapter.

Line-status detection of dial tone, ringback tone, busy, and incoming ring is provided along with automated routines which react to detected conditions.

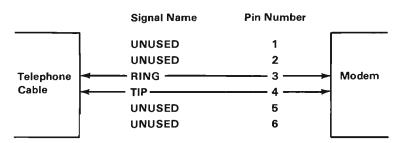

The modem card has one USOC RJ11 jack.

System I/O Channel

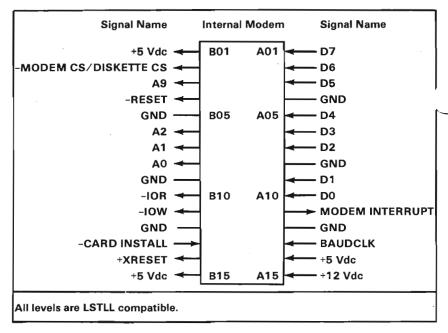

The following shows pin assignments for the system board modem connector. Pins A1 to A15 are on the component side.

Internal Modem Connectors

Connector Specifications (Part 1 of 2)

Connector Specifications (Part 2 of 2)

IBM PCjr Attachable Joystick

The Attachable Joystick is an input device intended to provide the user with two-dimensional positioning-control. Two pushbutton switches on the joystick give the user additional input capability.

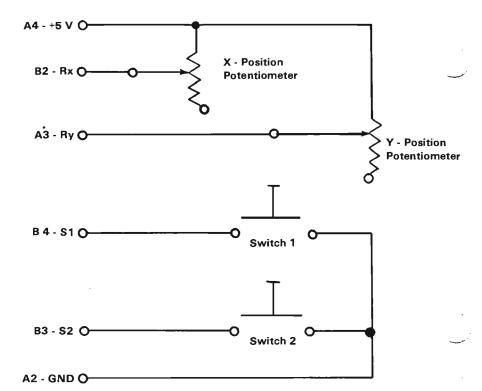

Hardware Description

Two modes of operation of the joystick are available. In the "Spring Return" mode the control stick returns to the center position when released. The "Free Floating" mode allows smooth, force free operation with the control stick remaining in position when released. Selection of these modes can be made for each axis independently. Two controls are provided for individual adjustment to the electrical center of each axis.

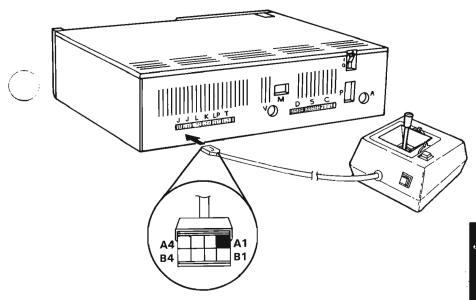

Functional Description

Positional information is derived from two potentiometers Rx and Ry. The resistance of these potentiometers will vary from 0 to 100K ohms nominally as the position of the control stick moves from left to right (X-axis) and from top to bottom (Y-axis). A linear taper is used on the potentiometers so that a linear relationship exists between angular displacement of the stick and the resulting resistance. Electrical centering for each axis is accomplished with the controls by mechanically rotating the body of the potentiometer. Adjustment in this manner has the effect of varying the minimum and maximum resistance relative to the extremes of the angular displacement. The two pushbuttons provided on the joystick are single-pole, single-throw, normally-open pushbuttons.

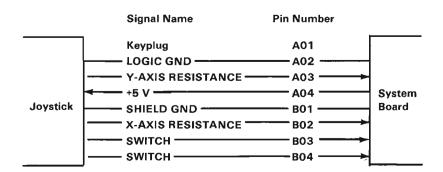

The following are the logic diagram and specifications for the two Attachable Joystick connectors.

Attachable Joystick Logic Diagram

Attachable Joystick Connector

Connector Specifications

Notes:

IBM Color Display

The IBM Color Display is a Red/Green/Blue/Intensity (RGBI)-Direct-Drive display, that is independently housed and powered.

Hardware Description

The IBM Color Display's signal cable is approximately 1.5 meters (5 feet) in length. This signal cable must be attached to the IBM PCjr with the IBM PCjr Adapter Cable for the IBM Color Display which provides a direct-drive connection from the IBM PCjr

A second cable provides ac power to the display from a standard wall outlet. The display has its own power control and indicator. The display will accept either 120-volt 60-Hz power or 220-volt 50-Hz power. The power supply in the display automatically switches to match the applied power.

The display has a 340 mm (13 in.) CRT. The CRT and analog circuits are packaged in an enclosure so the display may be placed separately from the system unit. Front panel controls and indicators include: Power-On control, Power-On indicator, Brightness and Contrast controls. Two additional rear-panel controls are the Vertical Hold and Vertical-Size controls.

Operating Characteristics

Screen

- High contrast (black) screen.
- Displays up to 16 colors.
- · Characters defined in an 8-high by 8-wide matrix.

Video Signal

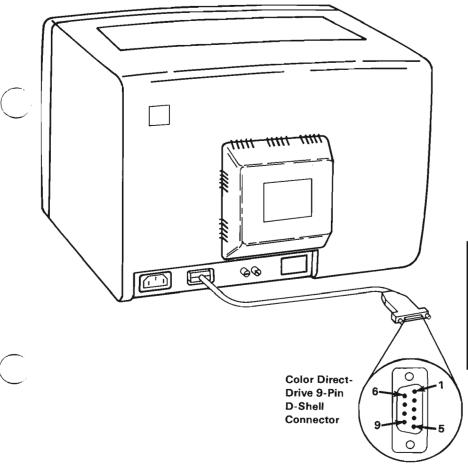

- Maximum video bandwidth of 14 MHz.
- Red, green, and blue video-signals, vertical sync, horizontial sync, and intensity are all independent.
 All input signals are TTL compatible.

Vertical Drive

 Screen refreshed at 60 Hz with 200 vertical lines of resolution.

Horizontal Drive

• The horizontal drive frequency is 15.75 kHz.

Color-Display Connector

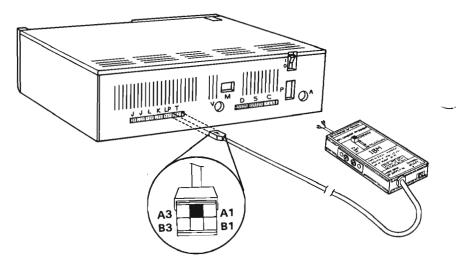

Connector Specifications

Notes:

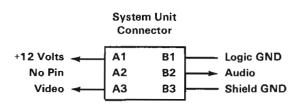

IBM Connector for Television

The Connector for Television is a sealed Radio Frequency (RF) Modulator that imposes the composite video and audio signals onto the RF carrier-wave supplied by the modulator. The connector unit has two two-position switches. One switch selects between the computer's signal or the standard-TV signal from an antenna as the input to the TV. The other switch selects either channel 3's or channel 4's carrier-wave frequency for input to the TV. This allows users to select the weaker TV channel for their area reducing the amount of interference with the computer's input signal. Signal input from the computer is provided by a five-conductor cable with a six-pin IBM PCjr-dedicated connector. Two spade-lug terminals provide for TV-antenna-cable connection. One twin-lead flat-type TV-cable provides input to the TV.

The following is the connector specifications for the IBM Connector for Television.

Connector for TV Connector

Connector Specifications

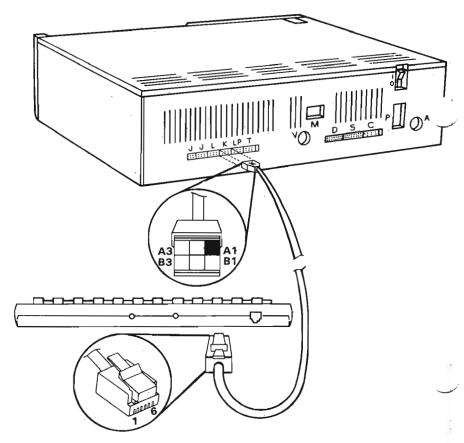

IBM PCjr Keyboard Cord

The IBM PCjr Cordless Keyboard can be attached to the PCjr using the optional Keyboard Cord. The Keyboard Cord is a 1.8 meter (6 foot), two twisted-pair cable, with a six-position RJ11-type connector for the keyboard and a six-position Berg-type connector for the system unit.

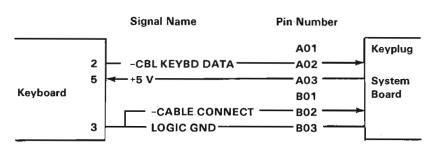

The Keyboard Cord option should be used in an environment that is unfavorable for use of the infra-red link. For instance, brightly lit high-intensity light areas, or multiple IBM PCjr areas where keyboards can conflict with one another.

Insertion of the cord's keyboard connector into the keyboard actuates switches internal to the keyboard. The switches 'deactivate' the IR transmitter by removing the power supplied by the keyboard's batteries. The system unit's infra-red (IR) receiver circuit is 'disabled' by the -CABLE CONNECT signal, supplied when the system-unit end of the cord is connected.

The following figures show the connector specifications for the Keyboard Cord.

Keyboard Cord Connectors

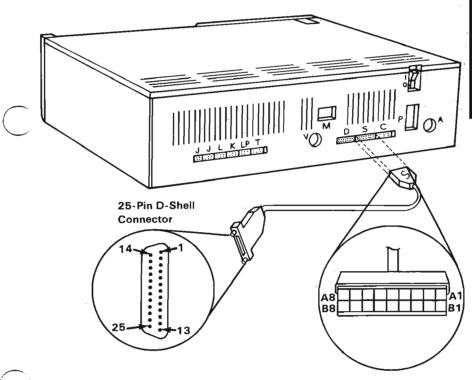

Connector Specifications

3-88 Keyboard Cord

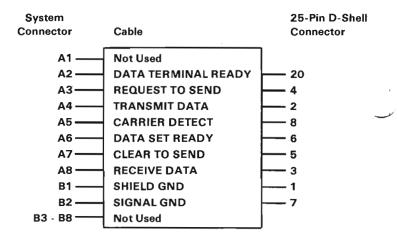

IBM PCjr Adapter Cable for Serial Devices

The Adapter Cable for Serial Devices is a 72 mm (3-inch) long, nine-conductor cable terminated with a 16-position Berg-type connector and a 25-pin "D"-shell connector. This cable allows serial devices that terminate with a standard EIA-RS232C 25-pin "D"-shell connector to be connected to the IBM PCjr.

The following figures show the connector specifications for the Adapter Cable for Serial Devices.

Adapter Cable for Serial Devices

Connector Specifications

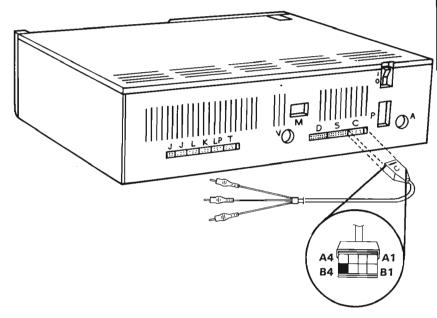

IBM PCjr Adapter Cable for Cassette

This option is an adapter cable that allows connection of a cassette recorder to the IBM PCjr cassette connector.

The cassette recorder to be connected must use the following type connectors:

- Belden Style-51 miniture phone-plug (Auxiliary)
- Belden Style-51 miniture phone-plug (Earphone)
- Belden Style-56 subminiture phone-plug (Remote)

The following figures show the connector specifications for the Adapter Cable for Cassette.

Adapter Cable for Cassette Connectors

Connector Specifications (Recorder End) (Part 2 of 2)

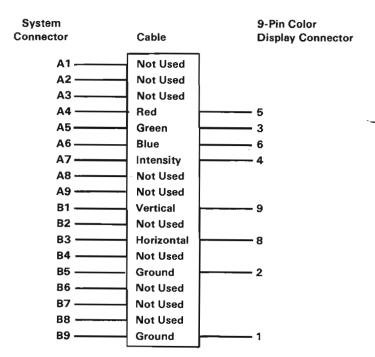

IBM PCjr Adapter Cable for the IBM Color Display

This adapter cable allows the IBM Color Display to be connected to the IBM PCjr.

The following figures show the connector specifications for the adapter cable for the IBM Color Display.

Adapter Cable for IBM Color Display Connectors

Connector Specifications

IBM PCjr Parallel Printer Attachment

The Parallel Printer Attachment is provided to attach various I/O devices that accept eight bits of parallel data at standard TTL-logic levels. The card measures 76mm (3 inches) high by 244mm (9.6 inches) long.

The Parallel Printer Attachment attaches as a feature to the right-hand side of the system unit. It connects to the 60-pin Input/Output (I/O) connector where power and system-input signals are received. A parallel printer attaches to the Parallel Printer Attachment through a 25-pin female "D"-shell connector located on the rear edge of the attachment, where a cable and shield can be attached. The logic design is compatible with the IBM Personal Computer printer adapter.

The attachment card has 12 TTL buffer-output points which are latched and can be 'written' and 'read' under program control using the processor 'IN' or 'Out' instructions. The attachment card also has five steady-state input-points that may be 'read' using the processors' 'IN' instructions.

In addition, one input can also be used to create a processor interrupt. This interrupt can be 'enabled' and 'disabled' under program control. 'Reset' from the power-on circuit is also **ORed** with a program-output point allowing a device to receive a power-on 'reset' when the processor is 'reset.'

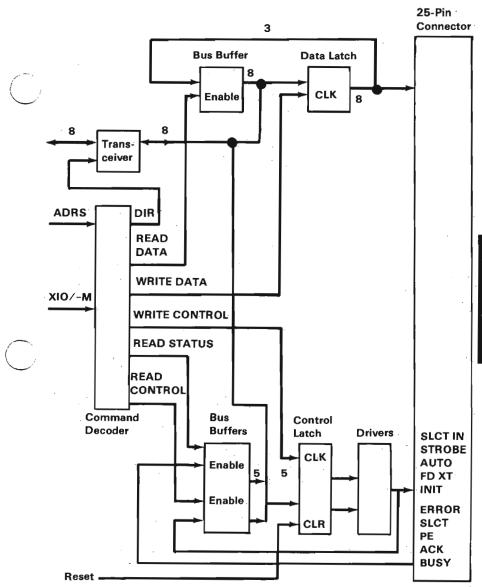

When the Parallel Printer Attachment is used to attach a printer, data or printer commands are loaded into an 8-bit latched output-port, then the strobe line is 'activated' to 'write' data to the printer. The program can then 'read' the input ports for printer

status indicating when the next character can be written or it may use the interrupt line to indicate **not busy** to the software.

The output ports can also be 'read' at the card's interface for diagnostic-loop functions. This allows fault-isolation determination between the printer attachment and the attached printer.

Description

During a system I/O 'read' or 'write', with the proper address selection, data may be 'written' to or 'read' from the Parallel Printer Attachment. The data and Control Registers must be manipulated by the system software to be consistent with the attaching hardware. The following is a block diagram of the Parallel Printer Attachment card.

Parallel Printer Interface Block Diagram

System Interface

The Parallel Printer Attachment reserves addresses hex 378, through hex 37F. IO/-M must also be 'active high' when addressing the Parallel Printer Attachment.

A card selected signal (-CARD SLCTD) is provided to the system I/O when the above addresses are used, and the IO/-M bit is 'active high.'

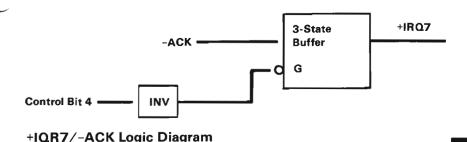

Specific commands are decoded from A0, A1, RD, and WR per the following table. Input A2 is not used.

Addresses (hex)	Operation	Comments
378	'Read'	Read Data Latch
379	'Read'	Read Status
37A	'Read'	Read Control Latch
37B	'Read'	Unused
37B	'Write'	Write Data Latch
379	'Write'	Unused
37A	'Write'	Write Control Latch
37B	'Write'	Unused

All data transfers take place over the 8-bit I/O data-bus with timing provided by the 8088 microprocessor. (IOR, IOW, IO/-M)

An interrupt is provided to the system through the I/O connector of the Parallel Printer Attachment. This

interrupt is 'positive active', Interrupt Level 7 (+IRQ7). Bit 4 of the control latch must be 'written high' to allow interrupts. When the -ACKnowledge signal ('low active' signal goes 'high') the I/O device causes a level 7 interrupt. See the following figure.

Programming Considerations

The Parallel Printer Attachment can serve as a general purpose peripherial driver. This section describes a configuration which supports attachment to the IBM Graphics Printer.

Command Definition

For the parallel-printer application, the following bit definitions apply.

Data Latch - Address hex 378

A 'write' to this address causes data to be latched onto the printer data bits. A 'read' from this address presents the contents of the data latch to the processor. MSB 3 0 **LSB** Data Data Data Data Data Data Data Bit Bit Bit Bit Bit Bit Bit Bit 7 6 5 4 3 2 1 0

Data Latch Format

Printer Status - Address hex 379, hex 7D, Input Only

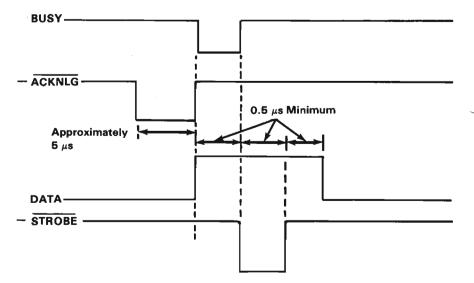

This port provides real-time feedback and status to the system from the printer.

Bit	Signal Name	Description
MSB 7	-BUSY	When this signal is at a low level, the printer is busy and cannot accept data. It can become low during data entry, off-line printing, head translation, or error state.
6	-ACK	When port B is read, this bit will represent the current state of the printer ACK signal. A low level means that a character has been received and the printer is ready to accept another. Normally, this signal will be low for approximately 5 microseconds before BUSY goes away.
5	-PE	A low level indicates that the printer has detected an end of form.
4	+SLCT	A high level indicates that the printer is selected.
3	-ERROR	A low level indicates that the printer has encounted an error condition.
2 Through 0 LSB		Unused.

Printer Status

Printer Control - Address hex 37A

This port contains printer control signals. A 'write' latches control bits to the printer; a 'read' presents the contents of the latches to the processor. See the following timing diagram:

Parallel Interface Timing Diagram

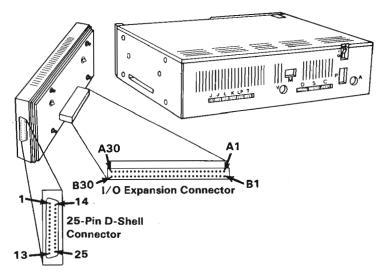

The following figure describes the printer control signals.

3-102 Parallel Printer Attachment

Bit	Signal Name	Description
MSB 7 Through 5		Unused.
4	+INTERRUPT ENABLE	A high level in this bit position will allow an interrupt to occur when -ACK goes high.
3	SLCT IN	A low level in this bit position selects the printer.
2	INIT	A low level will initialize the printer (50 microseconds minimum).
1	AUTO FD XT	A low level will cause the printer to line feed anytime a line is printed.
LSB0	STROBE	A 5 microsecond (minimum) low active pulse clocks data into the printer. Valid data must be present for 5 microseconds (minimum) before and after the STROBE pulse.

Printer Control Signal

The following are the connector specifications for the IBM PCjr Parallel Printer Attachment.

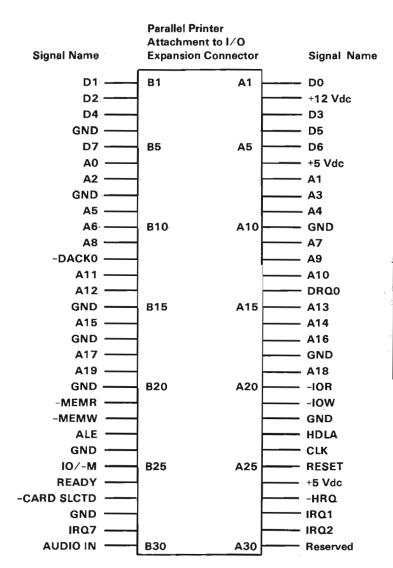

Parallel Printer Attachment Connectors

	25-Pin "D"-Shell Connector

Connector Specifications (Part 1 of 2)

3-104 Parallel Printer Attachment

Connector Specifications (Part 2 of 2)

Notes:

IBM Graphics Printer

The IBM Graphics Printer is a self-powered. stand-alone, tabletop unit which attaches to the system unit through a 6-foot parallel-signal cable, and obtains 120 Vac power from a standard wall outlet through a seperate cable. It is an 80 CPS (characters per second), bidirectional, wire-matrix device that can print in a compressed mode of 132 characters per line, in a standard mode of 80 characters per line, in a double width-compressed mode of 66 characters per line, and in a double width mode of 40 characters per line. It can also print double-size and double-strike characters. It prints the standard ASCII, 96-character, uppercase and lowercase character sets and also has a set of 64 special block characters. It has an extended character set for international languages, subscript, superscript, an underline mode, and programmable graphics. The Graphics printer accepts commands that set the line-feed control desired for the application.

It attaches to the system unit through the IBM PCjr Parallel Printer Attachment. The cable is a 25-conducter, shielded cable with a 25-pin "D"-shell connector at the system unit end, and a 36-pin connector at the printer end.

Printer Specifications

Print Method: Serial-impact dot matrix

Print Speed: 80 CPS

Print Direction: Bidirectional with logic seeking

Number of Pins in Head: 9

Line Spacing: 1/16 inch (4.23 mm) or programmable

Matrix Characteristics: 9 by 9

Character Set: Full 96-character ASCII with descenders plus 9 international characters/symbols

Graphic Characters: See "Additional Printer

Specifications"

Printing Sizes:

Normal 10 characters-per-inch with a

maximum of 80 characters-per-line

Double Width 5 characters-per-inch with a

maximum of 40 characters per line

Compressed 16.5 characters-per-inch with a

maximum of 132 characters per line

Double Width-Compressed

8.25 characters-per-inch with a maximum of 66 characters per line

Subscript 10 characters-per-inch with a

maximum of 80 characters per line

Superscript 10 characters-per-inch with a

maximum of 80 characters per line

Media Handling: Adjustable sprocket-pin-feed with 4-inch (101.6 mm) to 10-inch (254 mm) width paper, one original plus two carbon copies (total thickness not to exceed 0.012 inch (0.3 mm)), minimum paper thickness of 0.0025 inch (0.064 mm)

Interface: Parallel 8-bit data and control lines

Inked Ribbon: Black, cartridge type with a life

expectancy of 3 million characters

Environmental Conditions: Operating temperature is 5 to 35 degrees centigrade (41 to 95 degrees Fahrenheit), operating humidity is 10 to 80% non-condensing

Power Requirements: 120 Vac, 60 Hz, 1 A maximum with a power consumption of 100 VA maximum

Physical Characteristics:

 Height
 107 mm (4.2 inches)

 Width
 374 mm (14.7 inches)

 Depth
 305 mm (12 inches)

 Weight
 5.5 kg (12 pounds)

Additional Printer Specifications

Printing Characteristics

Extra Character Set

Set 1 Additional ASCII numbers 160 to 175 contain European

characters. Numbers 176 to 223 contain graphic characters. Numbers 224 to 239 contain selected Greek-characters. Numbers 240 to 255 contain

math and extra symbols.

Set 2 The differences in Set 2 are

ASCII numbers 3,4,5,6, and 21.

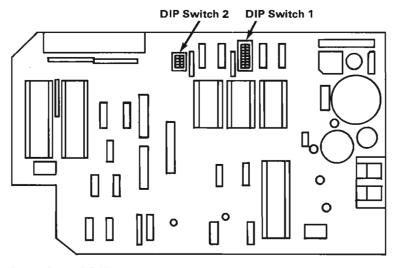

ASCII numbers 128 to 175 contain European characters.

Graphics There are 20 block characters and

programmable graphics.

DIP Switch Settings

There are two Dual-Inline-Package (DIP) switches on the control circuit-board. In order to satisfy the user's specific requirements, desired control modes are selected by the DIP switches. The functions of these switches and their preset conditions at the time of shipment are shown in the following figures.

Location of DIP Switches

Switch Number	Function	On	Off	Factory Position	
1-1	Not Applicable	_	_	On	
1-2	CR	Print Only	Print and Line Feed	On	
1-3	Buffer Full	Print Only	Print and Line Feed	Off	
1-4	Cancel Code	Invalid	Valid	Off	
1-5	Not Applicable	_	_	On	
1-6	Error Buzzer	Sound	No Sound	On	
1-7	Character Generator	Set 2	Set 1	Off	
1-8	SLCT IN Signal	Fixed Internally	Not Fixed Internally	On	

Functions and Conditions of DIP Switch 1

Switch Number	Function	On	Off	Factory Position
2-1	Form Length	12 Inches	11 Inches	Off
2-2	Line Spacing	1/8 Inch	1/6 Inch	Off
2-3	Auto Feed XT Signal	Fixed Internally	Not Fixed Internally	Off
2-4	1 Inch Skip Over Perforation	Valid	Invalid	Off

Functions and Conditions of DIP Switch 2

Parallel Interface Description

Specifications

Data Transfer Rate 1000 cycles-per-second

(cps)-(maximum)

Synchronization By externally-supplied

STROBE pulses

Signal Exchange

-ACKNLG or BUSY signals

Logic level Input data and all

interface-control signals are

compatible with the

Transistor-Transistor Logic

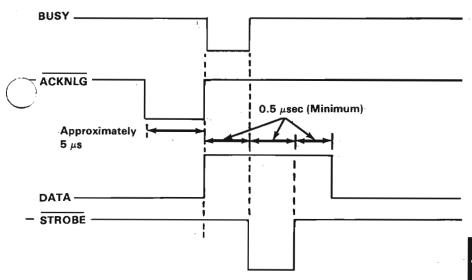

(TTL) level.

Connector Plug 57-30360 (Amphenol)

Connector-pin assignments and descriptions of respective interface-signals are provided in the following figures.

Data Transfer Sequence

The following figure shows the Parallel Interface Timing.

Parallel Interface Timing Diagram

Interface Signals

STROBE pulse to read data in. Pulse width must be more than 0.5 μ s at the receiving terminal. The signal is
normally 'high'; however read-in of
data is performed at the 'Low' level
of this signal.
These signals are the first to eight bits

These signals are the first to eight bit
of parallel data. Each signal is at a
'high' level when data is a logical 1
and 'low' when data is a logical 0.
Approximately 0.5 µs pulse (low)
indicates that data has been received

indicates that data has been received and the printer is ready to accept data. A 'high' signal indicates that the printer cannot receive data. The signal is 'high' in the following cases:

During data entry

-ACKNLG

BUSY

During printing operation

• In the "off-line" state

During printer-error status

PE A 'high' signal indicates that the

printer is out of paper.

SLCT This signal indicates that the printer is

in the selected state.

Auto Feed XT When this signal is 'low' paper is fed

one line after printing. This signal level can be fixed 'low' by DIP

switch pin 2-3.

INT When this signal is 'low' the printer

controller is reset to its initial state and the print buffer is cleared. This signal is normally 'high' and its pulse width must be more than 50 μ s at the

receiving terminal.

Error This signal is 'low' when the printer

is in the "Paper End," "Off Line,"

and "Error" state.

-SLCTIN Data entry to the printer is possible

only when this signal is 'low'. This signal can be fixed 'low' by DIP

switch 1-8.

Notes:

1. All interface conditions are based on TTL level. Both the rise and fall times of each signal must be less than $0.2 \mu s$.

 Data transfer must not be carried out by ignoring the -ACKNLG or BUSY signal. Data transfer can only occur after confirming the -ACKNLG signal or when the BUSY signal is 'low'.

The following figure shows the pin assignment and direction of each signal.

Signal	Signal Pin #	Return Pin #	Direction		
-STROBE	1	19	In		
DATA 1	2	20	In		
DATA 2	2 3	21	In		
DATA 3	4 5	22	In		
DATA 4	5	23	In		
DATA 5	6	24	In		
DATA 6	7	25	In		
DATA 7	8	26	In		
DATA 8	9	27	In		
-ACKNLG	10	28	Out		
BUSY	11	29	Out		
PE	12	30	Out		
SLCT	13	_	Out		
AUTO FEED XT	14	_	In		
NC	15		_		
OV	16	_	_		
CHASSIS GND	17	_	_		
NC	18		_		
GND	19-30	_

GND	33	_	· —		
NC	34		_		
	35		_		
-SLCT IN	36	_	In		

Pin Assignments

Printer Modes

The IBM Graphics Printer can use any of the combinations listed in the following table and the print of mode can be changed at any place within the line.

Modes can be selected and combined if they are in the same vertical column.

Printer Modes									
Normal	X	X	X						
Compressed	1			X	X	X			
Emphasized				1			X	X	X
Double Strike	X	1		X		1	X		l
Subscript		X			X			X	
Superscript			X			X		ļ	X
Double Width	X	X	X	X	X	X	X	X	X
Underline	X	X	X	X	X	X	X	X	X

Printer Modes

Printer Control Codes

On the following pages are complete codes for printer characters, controls, and graphics. You may want to keep them handy for future reference. The printer codes are listed in ASCII-decimal numeric-order (from NUL which is 0 to DEL, which is 127). The examples given in the Printer-Function descriptions are written in the BASIC language. The "input" description is given when more information is needed for programming considerations.

ASCII decimal values for the printer control codes can be found under "Printer Character Sets."

The Descriptions that follow assume that the printer DIP switches have not been changed from their factory settings.

Printer code NUL **Printer Function**

Null:

Used with ESC B and ESC D as a list terminator. NUL is also used with other printer.

control codes to select options (for example, ESC S).

Example:

LPRINT CHR\$ (0);

BEL

Bell:

Sounds the printer buzzer for 1 second.

Example:

LPRINT CHR\$(7);

HT

Horizontal Tab:

Tabs to the next horizontal tab stop. Tab stops are set with ESC D. Tab stops are set every 8 columns when the printer is powered on.

Example:

LPRINT CHR\$(9);

LF

Line Feed:

Spaces the paper up one line. Line spacing is 1/16-inch unless reset by ESC A, ESC 0, ESC 1, ESC 2, or ESC 3.

Example:

LPRINT CHR\$(10);

Form Feed:

Advances the paper to the top of the next page.

Note: The location of the paper, when the printer is powered on, determines the top of the page. The next top of page is 11 inches from that position. ESC C can be used to change the page length.

Example:

LPRINT CHR\$(12);

CR

Carriage Return:

Ends the line that the printer is on and prints the data remaining in the printer buffer. (No Line Feed operation takes place.)

Note: IBM Personal Computer BASIC adds a Line

Feed unless 128 is added [for example

CHR\$(141)].

Example:

LPRINT CHR\$(13);

SO Shift Out (Double Width):

Changes the printer to the Double-Width print-mode.

Note: A Carriage Return, Line Feed or DC4 cancels Double-Width print-mode.

Example:

LPRINT CHR\$(14);

SI Shift In (Compressed):

Changes the printer to the Compressed-Character

print-mode. Example: LPRINT CHR\$(15);

Device Control 1 (Compressed Off):

DC₂

Stops printing in the Compressed print-mode.

Example:

LPRINT CHR\$(18);

DC4 Device Control 4 (Double Width

Off):

Stops printing in the Double-Width print-mode.

Example:

LPRINT CHR\$(20);

CAN Cancel:

Clears the printer buffer. Control codes,

except SO, remain in effect.

Example:

LPRINT CHR\$(24);

ESC Escape:

Lets the printer know that the next data sent

is a printer command.

Example:

LPRINT CHR\$(27):

ESC -Escape Minus (Underline) Format: ESC -;n;

ESC - followed by a 1, prints all of the following

data with an underline.

ESC - followed by a 0 (zero), cancels the Underline

print-mode.

Example:

LPRINT CHR\$(27); CHR\$(45); CHR\$(1);

ESC 0 Escape Zero (1/8-Inch Line Feeding)

Changes paper feeding to 1/8-inch.

Example:

LPRINT CHR\$(27);CHR\$(48);

ESC 1 Escape One (7/72-Inch Line

Feeding)

Changes paper feeding to 7/72-inch.

Example:

LPRINT CHR\$(27); CHR\$(49);

ESC 2 Escape Two (Starts Variable

Line-Feeding)

ESC 2 is an execution command for ESC A. If no ESC A command has been given, line feeding

returns to 1/6-inch.

Example:

LPRINT CHR\$(27);CHR\$(50);

ESC 3 Escape Three (Variable

Line-Feeding)

Format: ESC 3;n;

Changes the paper feeding to n/216-inch. The example that follows sets the paper feeding to 54/216 (1/4)-inch. The value of n must be

between 1 and 255.

Example:

LPRINT CHR\$(27);CHR\$(51);CHR\$(54);

ESC 6 Escape Six (Select Character Set 2)

Selects Character Set 2. (See "Printer

Character set 2")

Example:

LPRINT CHR\$(27); CHR\$(54);

ESC 7 Escape Seven (Select Character Set 1)

Selects character set 1. (See "Printer

Character Set 1")

Character set 1 is selected when the printer is powered on or reset.

Example:

LPRINT CHR\$(27); CHR\$(55);

ESC 8 Escape Eight (Ignore Paper End)

Allows the printer to print to the end of the paper. The printer ignores the Paper End switch.

Example:

LPRINT CHR\$(27); CHR\$(56);

ESC 9 Escape Nine (Cancel Ignore Paper

End)

Cancels the Ignore Paper End command. ESC 9 is selected when the printer is powered on or reset.

Example:

LPRINT CHR\$(27); CHR\$(57);

ESC < Escape Less Than (Home Head)

The printer head returns to the left margin to print the line following ESC <.

This occurs for one line only.

Example:

LPRINT CHR\$(27); CHR\$(60);

ESC A Escape A (Sets Variable Line

Feeding)

Format: ESC A;n;

Escape A sets the line-feed to n/72-inch. The example that follows tells the printer to

set line feeding to 24/72-inch. ESC 2 must

be sent to the printer before the line

feeding changes. For example, ESC A;24 (text) ESC 2 (text). The text following ESC

A;24 spaces at the previously set

line-feed increments. The text following ESC

2 prints with new line-feed

increments of 24/72-inch. Any increment between 1/72 and 85/72-inch may be used.

Example:

LPRINT

CHR\$(27);CHR\$(65);CHR\$(24);

CHR\$(27);CHR\$(50);

Escape C (Set Lines-per-Page)

Format: ESC C;n;

Sets the page length. The ESC C command must

have a value following it to specify the

length of page desired. (Maximum form length

for the printer is 127 lines.) The example

below sets the page length to 55 lines. The printer defaults to 66 lines-per-page when

powered on or reset.

Example:

LPRINT CHR\$(27); CHR\$(67); CHR\$(55);

Escape C (Set Inches-per-Page)

Format: ESC C;n;m;

Escape C sets the length of the page in inches. This command requires a value of 0

(zero) for n, and a value between 1 and 22

for m.

Example:

LPRINT CHR\$(27); CHR\$(67); CHR\$(0); CHR\$(12);

ESC D Escape D (Sets Horizontal Tab Stops)

Format: ESC D;n1;n2;...nk;NUL;

Sets the horizontal-tab stop-positions. The

example that follows shows the horizontal-tab

stop-positions set at printer column

positions of 10, 20, and 40. They are

followed by CHR\$(0), the NUL code. They must.

also be in ascending numeric order as shown.

Tab stops can be set between 1 and 80. When

in the Compressed-print mode, tab stops can

be set up to 132.

The Graphics Printer can have a maximum of 28 tab stops. The HT (CHR\$(9)) is used to

execute a tab operation.

Example:

Printers 3-121

LPRINT

CHR\$(27);CHR\$(68);CHR\$(10)

;CHR\$(20);CHR\$(40);

CHR\$(0);

ESC E Escape E (Emphasized)

Changes the printer to the Emphasized-print mode. The speed of the printer is reduced to half speed during the Emphasized-print mode.

Example:

LPRINT CHR\$(27);CHR\$(69);

ESC F Escape F (Emphasized Off)

Stops printing in the Emphasized-print mode.

Example:

LPRINT CHR\$(27);CHR\$(70);

ESC G Escape G (Double Strike)

Changes the printer to the Double-Strike print-mode. The paper is spaced 1/216 of an inch before the second pass of the print

head.

Example:

LPRINT CHR\$(27); CHR\$(71);

ESC H Escape H (Double Strike Off)

Stops printing in the Double-Strike mode.

Example:

LPRINT CHR\$(27); CHR\$(72);

ESC J Escape J (Sets Variable Line Feeding)

Format: ESC J;n;

When ESC J is sent to the printer, the paper feeds in increments of n/216 of an inch.

The value of n must be between 1 and 255.

The example that follows gives a line feed of

50/216-inch. ESC J is canceled after the line feed takes place.

Example:

LPRINT CHR\$(27); CHR\$(74); CHR\$(50);

ESC K Escape K (480 Bit-Image Graphics

Mode)

Format ESC K;n1;n2;v1;v2;...vk;

Changes from the Text mode to the Bit-Image

Graphics mode. n1 and n2 are one byte, which specify the number of bit-image data bytes to be transferred. v1 through vk are the bytes of the bit-image data. The number of bit-image data bytes (k) is equal to n1 +256n2 and cannot exceed 480 bytes. At every horizontal position, each byte can print up to 8 vertical dots. Bit-image data may be mixed with text data on the same line.

Note: Assign values to n1 and n2 as follows: n1 represents values from 0 - 255. n2 represents values from 0 - 1 x 256.

MSB is most-significant bit and LSB is least -significant bit.

The following figures show the format.

MSB							LSB
27	2 ⁶	2 ⁵	24	2 ³	2 ²	21	2 ⁰

MSB							LSB
2 ¹⁵	2 ¹⁴	2 ¹³	2 ¹²	2 ¹¹	2 ¹⁰	2 ⁹	28

Data sent to the printer.

Text (20 characters)	ESC	K	n=360	Bit-image data	Next data
1 ' '				•	

In text mode, 20 characters in text mode correspond to 120 bit-image positions (20 x 6 = 120). The printable portion left in Bit-Image mode is 360 dot positions (480 - 120 = 360).

Data sent to the printer.

	n ₁ n ₂									$n_1 n_2$
Data A	ESC K	n ₁	n ₂	Data B	Data C	ESC	Κ	n ₁	n_2	Data D
Text data	Len data	igth o	f	Bit- image data	Text data	Le da	ngtl ta	n of		Bit- image data
480 bit-image dot positions										

Example: 1 'OPEN PRINTER IN RANDOM MODE WITH LENGTH OF 255

- 2 OPEN "LPT1:"AS #1
- 3 WIDTH "LPT1:",255
- 4 PRINT #1,CHR\$(13)+CHR\$(10);
- 5 SLASH=CHR\$(1)+CHR\$(02)
- +CHR\$(04)+CHR\$(08)
- 6 SLASH\$=SLASH\$+CHR\$(16)+CHR\$(32)
- +CHR&(64)+\$CHR\$(128)+CHR\$(0)
- 7 GAP\$=CHR\$(0)+CHR\$(0)+CHR\$(0)
- 8 NDOTS=480
- 9 'ESC K N1 N2
- 10 PRINT #1,CHR\$(27);"K";CHR\$(NDOTS MOD 256);CHR\$ (FIX(NDOTS/256));
- 11 'SEND NDOTS NUMBER OF BIT

IMAGE BYTES

12 FOR I=1 TO NDOTS/12 'NUMBER

OF SLASHES TO

PRINT USING GRAPHICS

13 PRINT #1,SLASH\$;GAP\$;

14 NEXT I 15 CLOSE 16 END

This example gives you a row of slashes printed in the Bit-Image mode.

Escape L (960-Bit-Image

Graphics-Mode)

Format: ESC L;n1;n2;v1;v2;...vk;

Changes from the Text mode to the Bit-Image Graphics mode. The input is similar to ESC K. The 960 Bit-Image mode prints at half the speed of the 480 Bit-Image Graphics mode, but can produce a denser graphic image. The number of bytes of bit-image Data (k) is n1 +256n2 but cannot exceed 960. n1 is in the

range of 0 to 255.

Escape N (Set Skip Perforation)

Format ESC N;n;

Sets the Skip Perforation function. The number following ESC N sets the value for the number of lines of Skip Perforation. The example shows a 12-line skip perforation. This prints 54 lines and feeds the paper 12 lines. The value of n must be between 1 and 127. ESC N must be reset anytime the page length (ESC C) is changed.

Example:

LPRINT CHR\$(27); CHR\$(78); CHR\$(12);

Escape O (Cancel Skip Perforation)
Cancels the Skip Perforation function.

Example:

LPRINT CHR\$(27); CHR\$(79);

Escape S (Subscript/Superscript)

Format: ESC S;n;

Changes the printer to the Subscript print mode when ESC S is followed by a 1, as in the example that follows. When ESC S is followed by a 0 (zero), the printer prints in the

ESC N

ESC O

ESC S

Superscript print mode.

Example:

LPRINT CHR\$(27); CHR\$(83); CHR\$(1);

ESC T Escape T (Subscript/Superscript Off)

The printer stops printing in the Subscript

or Superscript print mode.

Example:

LPRINT CHR\$(27); CHR\$(84);

Escape U (Unidirectional Printing) ESC U

Format: ESC U;n;

The printer prints from left to right

following the input of ESC U;1. When ESC U is followed by a 0 (zero), the left to right

printing operation is canceled. The

Unidirectional print-mode (ESC U) ensures a

more accurate print-start position for better print quality.

Example:

LPRINT CHR\$(27);CHR\$(85);CHR\$(1);

ESC W Escape W (Double Width)

Format: ESC W:n:

Changes the printer to the Double-Width print mode when ESC W is followed by a 1. This mode is not canceled by a line-feed operation and must be canceled with ESC W followed by a

0 (zero). Example:

LPRINT CHR\$(27); CHR\$(87); CHR\$(1);

Escape Y (960 Bit-Image Graphics ESC Y

Mode Normal Speed)

Format: ESC Y n1;n2;v1;v2;...vk;

Changes from the Text mode to the 960

Bit-Image Graphics mode. The printer prints at normal speed during this operation and

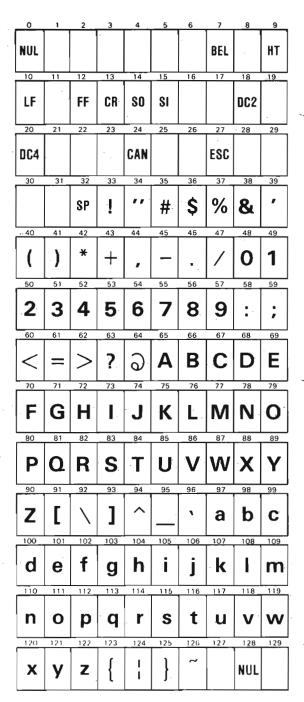

cannot print dots on consecutive dot position. The input of data is similar to

ESC L.

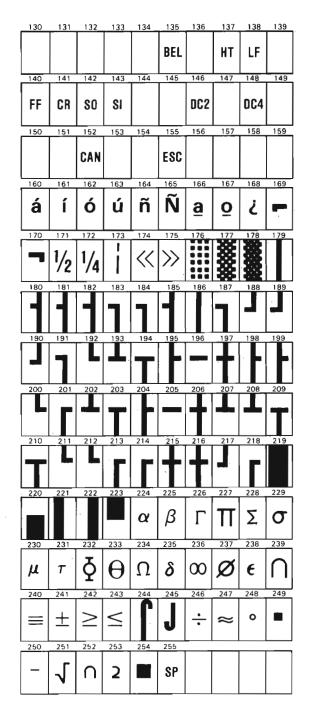

Escape Z (1920 Bit-Image Graphics ESC Z

Mode)

Format: ESC Z;n1;n2;v1;v2;...vk; Changes from the Text mode to the 1920 Bit-Image Graphics mode. The input is similar to the other Bit-Image Graphics modes. ESC Z can print only every third dot position.

Printer Character Set 2 (Part 1 of 2)

3-130 Printers

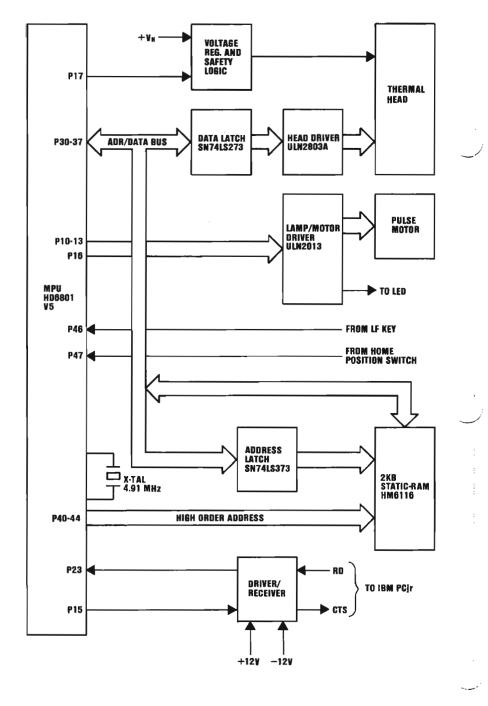

Printer Character Set 2 (Part 2 of 2)

Notes:

IBM PC Compact Printer

The PC Compact Printer is a stand-alone, tabletop unit that plugs into a standard wall outlet. Using an eight-wire print head, the printer can print characters from the standard ASCII, 96-character, uppercase and lowercase character sets, and prints the characters in a 5-by-7 dot matrix at 56 characters-per-second (cps). It prints in one direction (left-to-right) and has four print modes. In the standard mode, the printer prints 80 characters-per-line; in the compressed mode, 136 characters; in the double-width mode, 40 characters, and in the compressed double-width mode, 68 characters-per-line. The PC Compact Printer can also underline characters, has an extended character-set for international languages, and can accept special characters programmed by the user.

The printer has a 1.89 meter (6-foot), 16-lead, printer cable that connects, through an Amphenol connector, to the serial port (RS-232-C) at the rear of the system unit.

System Options

Printer Specifications

Print Method: Thermal, non-impact,

Dot-matrix

Dot-matrix

Print Speed: 56 cps

Print Direction: Left to right only

Number of Pins in 8

Print Head:

Line Spacing:

4.23 mm (1/6 in)

Matrix Pattern: 5 by 7 Dots

Character Set: Full 96-character ASCII

with descenders, plus

international

characters/symbols

Graphics: None

Print Modes:	Characters per Inch	Maximum Characters per Line		
Standard	10	80		
Double Width	5	40		
Compressed	17.5	136		
Compressed/	8.75	68		

Paper Feed: Friction Feed

Paper Width: 216 mm (8.5 in)

Copies: Single sheet only

Paper Path: Top

System Interface: Serial Data and Control Lines

Print Color: Black only

System Options

Print Mode Combinations for the PC Compact Printer

The following figure shows the print-mode combinations possible with the PC Compact Printer. Modes shown in the same column can be combined. A print mode can be changed at any time within a line: however, the double-width mode effects the entire line.

	M	Iodes			
Standard	xxx				
Compressed		XXX		XXX	xxx
Double-Width			xxx	xxx	xxx
Underline	xxx	xxx	xxx		xxx

Printer Control Codes and Functions

On the following pages you will find a detailed list of the printer control codes and functions. This list also includes descriptions of the functions and examples of the printer control codes.

The examples (LPRINT statements) given in the detailed descriptions of the printer control codes and functions list, are written in BASIC. Some knowledge of BASIC programming is needed to understand these codes. Some of the printer control codes also show a "Format" description when more information is needed for programming considerations.

CODE PRINTER FUNCTION

CAN Cancel

Clears the printer buffer. Control codes, except SO, remain in effect. Reinitializes the printer to the power on defaults.

LPRINT CHR\$(24);

CR Carriage Return

Ends the line the printer is on and prints any data remaining in the printer buffer. The logical character position is moved to the left margin. (No Line Feed operation takes place.) Note: IBM Personal Computer BASIC adds a Line Feed unless 128 is added.

LPRINT CHR\$(13);

DC2 Device Control 2 (Compressed Off)

Stops printing in the Compressed mode.

LPRINT CHR\$(18);

DC4 Device Control 4 (Double Width Off)

Stops printing in the Double Width mode.

LPRINT CHR\$(20);

ESC Escape

Informs the printer that the following data is a printer command. (See the following ESC commands.)

LPRINT CHR\$(27);

ESC B Escape B (Set Vertical Tabs)

Sets vertical tab stop positions. Up to 64 vertical tab stop positions are recognized by the printer. Tab stop positions must be received in ascending numeric order. The tab stop numbers do not become valid until you type the NUL code. Once vertical tab stops are established, they are valid until new tab stops are specified. (If the printer is reset or switched Off, set tab stops are cleared.) If no tab stop is set, the Vertical Tab command acts as a Line Feed command. ESC B followed only by NUL cancels tab stops. The form length must be set by the ESC C command prior to setting tabs.

LPRINT CHR\$(27);CHR\$(66);CHR\$(10);CHR\$(20); CHR\$(40);CHR\$(0);

ESC C Escape C (Set lines per page)

Format: ESC C;n; Sets the page length. The ESC C command must be followed by a value to specify the length of page desired. (Maximum form length for the printer is 127 lines.) The following example sets the page length to 55 lines. The printer default is 66 lines per page when switched On or reset.

LPRINT CHR\$(27);CHR\$(67);CHR\$(55);

ESC D Escape D (Set Horizontal Tab Stops)

Sets the horizontal tab stop positions. The following example shows the horizontal tab stop positions set at printer column positions of 10, 20 and 40. The horizontal tab stops are followed by CHR\$(0), the NUL code. They must also be in ascending numeric order as shown. You can set tab stops between 1 and 80. When in the Compressed print mode, you can set tabs up to column 136. The maximum number of tabs that can be set is 112. HT (CHR\$(9)) is used to execute a tab operation.

LPRINT

CHR\$(27);CHR\$(68);CHR\$(10)CHR\$(20) CHR\$(40);CHR\$(0);

ESC K Escape K (480 Bit-Image Graphics Mode)

Format: ESC K;n1;n2; v1; v2;.....vk; Changes the printer to the Bit-Image Graphics mode. Dot density is 82.5 by 82.5 dots per inch. If the graphics data exceeds the space remaining on the line, the printer ignores the excess data. Only the excess data is lost.

The numbers n1 and n2 specify, in binary form, the number of bit image data bytes to be transferred. Assign values to n1 to represent values from zero to 255 and assign values to n2 to represent values from 0-1 x 256. The total number of bit image data bytes cannot exceed 480. (n1 + (n2 X 256)).

The bit-image data bytes are v1 through vk.

All eight of the print head wires are used to print Bit-image graphics. Each bit of a bit-image data byte represents a dot position within a vertical line. The least significant bit (LSB) represents the bottom dot position, and the most significant bit (MSB) represents the top dot position. For example, if vX is hex 80, the top dot will print only in that vertical position; if vX is hex 01, the bottom dot will print; and if vX is hex FF, all eight dots will print.

Dot Bit Number

Top O---8

O - - - 7

O - - - 6

O - - - 5

0 - - - 4

O - - - 3

O - - - 2

Bottom O---1

LPRINT CHR\$(27);CHR\$(75);n1;n2

ESC N Escape N (Set Skip Perforation)

Format: ESC N;n; Sets the Skip Perforation function. The number following ESC N sets the number of lines to be skipped. The example shows a 12-line skip perforation. This command will print 54 lines and feed the paper 12 lines. The value of n must be between 1 and 127. ESC N must be reset anytime the page length (ESC C) is changed. The default for skip perforation is 25.4 mm (1 inch).

LPRINT CHR\$(27);CHR\$(78);CHR\$(12);

- ESC O Escape O (Cancel Skip Perforation)

 Cancels the Skip Perforation function.

 LPRINT CHR\$(27); CHR\$(79);
- ESC R Escape R (Clear Tabs)

 Resets all tab stops, both horizontal and vertical to the powered-on defaults.

 LPRINT CHR\$(27);CHR\$(82);
- ESC W Escape W (Double Width)
 Format: ESC W;n; Changes the printer to the Double Width mode when ESC W is followed by 1. This mode is not canceled by a line feed operation. It is canceled when ESC W is followed by 0 (zero).

 LPRINT CHR\$(27);CHR\$(87);CHR\$(1);
- ESC 0 Escape Zero (1/9-Inch Line Feed)
 Changes the line feed to 2.82 mm (1/9 inch).
 LPRINT CHR\$(27);CHR\$(48);
- ESC 1 Escape One (1/9-inch Line Feed)
 Changes the line feed to 2.82 mm (1/9 inch). ESC 1 functions the same as ESC 0.
 LPRINT CHR\$(27); CHR\$(49);
- ESC 2 Escape Two (Start Variable Line Feeding)
 Resets line spacing to 4.23 mm (1/6 inch).
 This is the powered-on default for vertical line spacing.
 LPRINT CHR\$(27);CHR\$(50);
- ESC 5 Escape Five (Sets Automatic Line Feed)
 With automatic line feed on, when a CR
 code is received, a line feed automatically
 follows after the carriage return. ESC 5 (1)
 sets auto line feed; ESC 5 (0) resets it.
 LPRINT CHR\$(27);CHR\$(53);

ESC - Escape Minus (Underline)

Format: ESC -;n; ESC - followed by 1, prints all of the following data with an underline. ESC - followed by 0 (zero), cancels the Underline print mode.

LPRINT CHR\$(27);CHR(45);CHR\$(1); [or CHR\$(0);]

ESC < Escape Less Than (Home Head)

The print head returns to the left margin to print the line following ESC <. This occurs for one line only.

LPRINT CHR\$(27);CHR\$(60);

FF Form Feed

Advances the paper to the top of the next page. Note: The location of the paper, when the printer power switch is set to the On position, determines the top of the page. The next top-of-page is 279 mm (11 inches) from that position. ESC C can be used to change the page length. Always separate multiple Form Feed commands with spaces. LPRINT CHR\$(12);

HT Horizontal Tab

Tabs to the next horizontal tab stop. Tab stops are set with ESC D. (Tab stops are automatically set at every 8 columns when the printer power switch is set to the On position.)

LPRINT CHR\$(9);

LF Line Feed

Advances the paper one line. Line spacing is 4.23 mm (1/6 inch) unless reset by ESC 0, ESC 1, ESC 2.

LPRINT CHR\$(10);

NUL Null

Used with ESC B and ESC D as terminator for the tab set and clear commands.

LPRINT CHR\$(0);

SI Shift In (Compressed On)

Changes the printer to the Compressed Character mode. This command is canceled by a DC2 code (Compressed Off). LPRINT CHR\$(15);

SO Shift Out (Double Width)

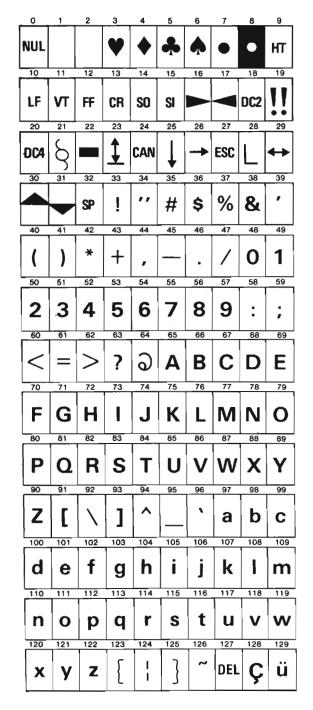

Changes the printer to the Double Width mode. Note: A Carriage Return, Line Feed or DC4 code cancels Double Width mode. LPRINT CHR\$(14):

VT Vertical Tab

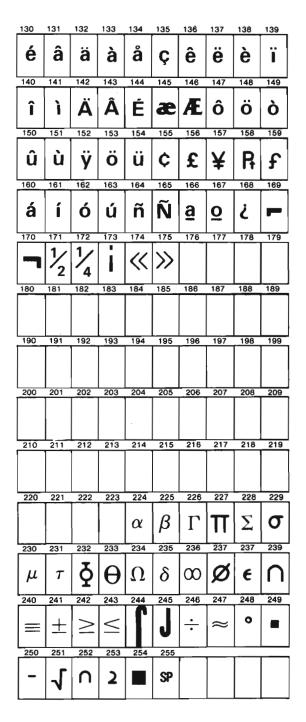

Spaces the paper to the next vertical tab position. VT are set by the ESC B sequence. The VT command is the same as the LF command, if no tabs are set. The paper is advanced one line after printing or advanced to the next vertical tab stop.

LPRINT CHR\$(11);

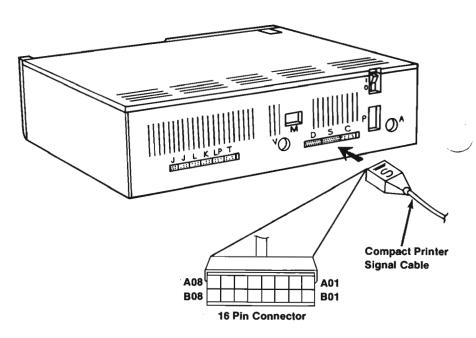

The following charts list the printer control codes and characters in ASCII decimal numeric order, (for example, NUL is 0 and ESC W is 87).

Notes:

Compatibility Overview

The IBM PCjr is a different Computer than the IBM Personal Computer and IBM Personal Computer XT. Even though it is different, the IBM PCjr has a high level of programming compatibility with the IBM Personal Computers. It is possible to create PCjr software applications that can run without modification on other IBM Personal Computers. In order to create such programs or to assess if a current program is compatible, you must understand the differences between the Personal Computers in the IBM family and know the proper way to communicate with them.

Normally, it would be impossible for a program written for one computer to run on a different computer since the microprocessors would be different; and the language of the application could not be executed by different processors. In this case, the application would have to be re-written entirely in the language of the other processor. Since the IBM PCjr and the other IBM Personal Computers use exactly the same microprocessors (Intel 8088), most assembler language programs need not be modified.

This alone is not enough, since applications normally take advantage of a computers device services (BIOS) and operating system (IBM DOS 2.1). In order to allow for maximum program compatibility, the IBM PCjr has maintained all BIOS system interrupts and utilizes the same IBM DOS. This means that applications which use the BIOS and the IBM DOS interrupts on the IBM Personal Computers operate the same on the IBM PCjr.

Note: The BIOS micro-code of the IBM PCjr is not identical to that of the IBM Personal Computers. If an application bypasses the BIOS interrupt calls and

directly accesses routines and/or storage locations in one system, it may not run in the other system. Some routines may be similar and some BIOS storage locations may be the same. It is strongly recommended that applications use only the BIOS and DOS interrupt interfaces in order to achieve compatibility in the IBM Personal Computer family.

Using the same language and the BIOS and DOS interfaces go a long way in achieving application compatibility. However, there are still several factors which need to be taken into consideration:

- Timing Dependencies
- Unequal Configurations
- Hardware Differences

Timing Dependencies

Programs running in user read/write memory normally run slower on the PCjr than on the IBM Personal Computers. Programs running in read-only memory (ROM) normally run a little faster on the PCjr than on the IBM Personal Computers. This may or may not cause a difference depending upon the application. Most applications are very I/O dependent in which case the execution time is not the critical factor and may not be noticeable. In other cases, the application runs the same but merely take a different amount of time.

If an application has very critical timing dependencies, any timing differences (faster or slower) may adversely affect its usability. Using an application's program execution speed to achieve a desired timing can effect the application. In these cases, the application may need to be modified.

Note: It is strongly recommended not to depend on instruction execution speed to achieve specific application timing. The system timer can provide short interval timing for assembly language programs. Similar timing functions are available in BASIC.

Performance of specific I/O devices (such as diskette or printer) may also differ between the PCjr and the other IBM Personal Computers. You should also avoid using timing of any I/O device as a dependency for the application.

Notes:

Unequal Configurations

In designing an application to run on both the IBM PCjr and the IBM Personal Computers, you need to make sure that the required hardware configuration is available on all machines. This means the application's minimum requirements are met by all IBM Personal Computers.

Notes:

Hardware Differences

To be able to run on either computer without change, an application utilizing a specific I/O device must have access to identical devices (or devices with identical operating characteristics and interfaces). The IBM PCjr and the IBM Personal Computers have very compatible I/O device capabilities.

The following table lists the hardware features and I/O devices supported by the IBM PCjr and the IBM Personal Computers and summarizes the differences:

Device	PC	PCXT	PCjr	PCjr Comments
Maximum User Memory	640KB	640KB	128KB	Shares user RAM with Video Buffer
Cordless Keyboard	No	No	Yes	Scan codes compatible and full 83 key capability
83 Key Keyboard	Yes	Yes	No	Compatible, but Hardware interface differences
Diskette Drive	Yes	Yes	Yes	Compatible, but different address and no DMA support
Hard Disk File	No	Yes	No	•
Parallel Printer	Yes	Yes	Yes	Compatible
RS 232 Serial Port	Yes	Yes	Yes	Compatible, hex 2F8 address, Interrupt Level 3, Baud-Rate-Frequency divisor difference
Game Control	Yes	Yes	Yes	Compatible interface with potential timing differences
Cassette	Yes	No	Yes	Compatible
Internal Modem	No	No	Yes	Compatible to PC Serial Port hex 3F8 address, Interrupt Level 4, frequency divisor difference
IBM Monochrome Display	Yes	Yes	No	
Color Graphics and Display	Yes	Yes	Yes	Compatible, with some register differences and enchancements
Light Pen	Yes	Yes	Yes	Compatible

PCjr and Personal Computers Comparison (Part 1 of 2)

4-10 Hardware Differences

Device	PC	PCXT	PCjr	PCjr Comments
Attachable Joystick	Yes	Yes	Yes	Compatible
8253 Timer (time of day)	Yes	Yes	Yes	Compatible
8259 Interrupt	Yes	Yes	Yes	Some difference in interrupt levels
Internal Sound	Yes	Yes	Yes	Compatible but less frequency response
TI 76496 Sound	No	No	Yes	
ROM Cartridge Interface	No	No	Yes	
Future I/O ROM Architecture	Yes	Yes	Yes	Compatible

PCjr and Personal Computers Comparison (Part 2 of 2)

The hardware differences between the IBM PCjr and the IBM Personal Computers may lead to incompatibilities depending upon the specific application. Once again; if your application maintains an interface to the Personal Computer Family at the BIOS and DOS interrupt levels, then all hardware differences are handled transparently to your application. If your application goes below the BIOS level and directly addresses the hardware, then there could be an incompatibility.

User Read/Write Memory

Memory difference can be a problem even with programs written for the same computer, if the available memory is not the same from one machine to the next. Thus, the deciding factor is to state what the minimum memory requirement is for the application, and require that amount on the computer in question.

It is important to understand the memory aspects of the IBM PCjr in relationship to that of the IBM Personal Computers. The IBM PCjr can be configured for 64K bytes or 128K bytes (with memory expansion). However, this user memory is not all available to the application. The IBM PCir video architecture utilizes a minimum of 16K bytes (in graphic mode) and 2K bytes (in alpha numeric mode) for the screen buffer. Therefore (in graphics mode), the IBM PCjr really has 48K bytes or 112K bytes (with memory expansion) available for system software. This is not the case with the IBM Personal Computers, since the color graphics adapter contains a separate 16K byte screen buffer. Thus, a 64K bytes Personal Computer with color graphics (extra 16K bytes) is an 80K byte system compared to a 64K byte IBM PCjr. The IBM PCjr also has graphic enhancements which allow more than the 16K bytes to be utilized for video screen buffers. If these enhanced features are used in an application, then even less is available for user memory.

Another aspect of available memory is the amount taken away by operating systems and language interpreters. In the case of the IBM DOS, both the IBM PCjr and the IBM Personal Computers support the same DOS. If your application requires the BASIC interpreter, then there may be a difference. The IBM Personal Computer Cassette BASIC resides entirely in the system ROM; taking no user memory. However, Disk BASIC or Advanced BASIC utilizes

approximately 10K bytes and 14K bytes respectively from user memory. In the IBM PC*jr*, Advanced BASIC capabilities (cartridge BASIC) reside in ROM, taking no user memory.

As you can see, many items factor into user available memory requirements. The most frequent comparison is for the assembler language or compiled application using a 16K-byte screen buffer operating under DOS 2.1. In this case, an application requiring 64K bytes of user memory on an IBM Personal Computer cannot run on the IBM PCjr without its expansion memory (128K byte capability). This is because of the IBM PCjr video usage of 16K bytes. Also, any application requiring more than 112K bytes of user memory with DOS 2.1 on the IBM Personal Computers cannot run on an IBM PCjr.

Diskette Capacity/Operation

Since the IBM PCjr maximum stand-alone configuration is one diskette drive with a maximum capacity of 360K bytes diskette storage, an IBM PCjr application is either limited by this diskette capacity or is impacted by the user having to change diskettes more frequently. The IBM Personal Computers can have multiple diskette drives with a capacity of 360K bytes diskette storage each or even possess hard files with a much larger disk storage capacity. This capacity difference may or may not be a concern depending upon the specific application.

In terms of diskette interfacing, the IBM PCjr and the IBM Personal Computers both utilize the NEC μ PD765 floppy diskette controller, but with different hardware addresses, and the IBM PCjr does not operate through direct memory access (DMA). Since the IBM PCjr does not have DMA capability, application programs

cannot overlap diskette I/O operations. When diskette I/O takes place, the entire system is masked (operator keystrokes and asynchronous communications cannot take place). Therefore, the application must insure that asynchronous operations do not take place while diskette I/O is active.

IBM PCjr Cordless Keyboard

The Cordless Keyboard is unique to the IBM PCjr. Even though it does not possess all 83 keys of the IBM Personal Computers' keyboards, it does have the capability to generate all of the scan codes of the 83-key keyboard.

The following shows the additional functions available on the PCjr.

PCjr Special Functions	Required Key Combinations
Shift screen to the left Shift screen to the right Audio Feedback (System	Alt + Ctrl + cursor left Alt + Ctrl + cursor right Alt + Ctrl + Caps Lock
clicks when a key is pressed. Customer Diagnostics	Alt + Ctrl + Ins

PCjr Special Functions

For more detail see "Keyboard Encoding and Usage" in Section 5.

Since all scan codes can be generated, any special application requirements can be met on the Cordless Keyboard.

The highest level of compatibility to interface to keyboards is through BIOS Interrupt hex 16 (read keystroke). Below that level is risky since there are hardware differences between the PCjr keyboard and the IBM Personal Computers' keyboards. The PCjr system utilizes the non-maskable (NMI) Interrupt to deserialize the scan codes and pass it to Interrupt hex 48 for compatible mapping to 83-key format. Interrupt level 9 remains a compatible interface for 83-key scan-code handling. It is not recommended to replace Interrupt level 9 even though a high degree of compatibility is maintained. If necessary, analyze this architecture carefully.

Color Graphics Capability

The IBM PCjr color graphic architecture is quite different from that of the IBM Personal Computers. The main difference (as previously discussed) is that the video buffer is taken from main user memory rather than having separate memory for video (as in the IBM Personal Computers). Normally, this would be an incompatibility since applications directly address the color graphics buffer at hex B8000. However, the IBM PCir has special hardware to redirect hex B8000 addressing to any specific 16K-byte block of its user memory. The IBM PCjr defaults the video buffer to the high end 16K-byte block of user memory and applications can continue to address the video buffer at hex B8000. In addition all IBM Personal Computers' color graphics adapter modes are BIOS compatible and memory structure (bit map) compatible. These modes are:

Modes	Requirements
Alphanumeric: 40x25 BW	None
40x25 Color	None
80x25 Color 80x25 BW	Note None
Graphics:	
320x200 4 Color	None
320x200 BW	None
640x200 BW	None
Note: PCjr requires	s the 64KB Memory and Display Expansion.

Modes Available on the IBM Personal Computers and PCjr

In addition the IBM PCjr provides some new enhanced graphic modes which are not available to the IBM Personal Computers.

Modes	Requirements	
Graphics:		
320x200 16 Color	Note	
640x200 4 Color	Note	
160x200 16 Color	None	
	the 64KB Memory and Display Expansion	

Modes Available Only on PCjr

The IBM PCjr and IBM Personal Computers utilize the 6845 controller, but the hardware interface is not completely the same. Hardware addresses hex 3D8 and

hex 3D9 are not supported by the IBM PCjr video interface. Requests using these two addresses are not honored.

Also there are differences in the actual video used by the hardware. BIOS maintains compatibility by using the appropriate PCjr video parameters (addressed through Interrupt hex 1D) and maintains all video calls (through Interrupt hex 10). Application can still specify video parameter overrides by modifying Interrupt hex 1D to address their own parameters; however, since there are hardware differences the recommended approach is as follows:

- 1. Copy the original parameters from the BIOS of the system.
- 2. Change only those parameters desired.
- 3. Consider the specific video differences between systems.

Other differences to be aware of are:

- The IBM PCjr defaults the colorburst mode to be off, whereas the IBM Personal Computers default colorburst to on. Thus applications should not assume either default but set colorburst mode (through BIOS call) to the desired setting.
- The IBM PCjr video supports a full gray scale capability which the IBM Personal Computers do not.
- There can be some color differences between the IBM Personal Computers and the IBM PCjr; especially when color mixing techniques are used.

Black and White Monochrome Display

The IBM PCjr does not support the IBM Personal Computers black and white monochrome display. Programs which directly address the IBM Personal Computers monochrome display are not compatible. For example, any direct addressing of the B&W video buffer at hex B8000 is not redirected by the IBM PCjr. Applications should support Personal Computer video capabilities through BIOS, and the video buffer address is either transparent to the application or the address is provided indirectly in the BIOS data area.

RS232 Serial Port and IBM PCjr Internal Modem

The IBM PCjr serial port address is hex 2F8 and is associated with hardware Interrupt level 3. This is compatible with a second Asynchronous Communications Adapter on the IBM Personal Computers. The Internal Modem address is hex 3F8 and is associated with Interrupt level 4. This is compatible with the first Asynchronous Communications Adapter on the IBM Personal Computers. It is important to note that when the IBM PCjr has the Internal Modem installed it is logically COM1 and the RS232 serial port is logically COM2 in BIOS, DOS, and BASIC. Without the Internal Modem installed the RS232 serial port is logically addressed as COM1 in BIOS, DOS, and BASIC even though its address is still hex 2F8 using Interrupt level 3. Other hardware differences on the PCjr serial devices are:

- A different frequency divisor is needed to generate baud rate. This is transparent to applications using BIOS to initialize the devices (Interrupt Hex 14).
- No ring indicate capability on the RS232 serial port.

Asynchronous communications input cannot be overlapped with IBM PCjr diskette I/O. Since diskette I/O operates in a non-DMA mode any asynchronous data received during diskette activity may be overrun (and lost). Thus, applications must insure that no diskette activity is active while receiving asynchronous communication data. This can be done by pacing the asynchronous device (tell it to hold from sending). The ASCII characters XOFF and XON are frequently used by some host computers for this purpose.

Summary

In summary, the IBM PCjr is a member of the IBM Personal Computer family by way of its strong architecture compatibility. The highest degree of application compatibility can be achieved by using a common high level language, and/ or accessing the system only through BIOS and DOS interrupts. It's not recommended to go below the BIOS level even though there are other hardware compatibilities. When it is necessary to design for particular computer differences, the application should determine at execution time which particular computer it is running on. This can be done by inspecting the ROM memory location at segment address hex F000 and offset hex FFFE for the following values

hex FF = the IBM Personal Computer hex FE = the IBM Personal Computer XT

 $\mathbf{hex} \; \mathbf{FD} \qquad = \mathbf{the} \; \mathbf{IBM} \; \mathbf{PC} \mathbf{jr}$

Once determined, dual paths would handle any differences.

ROM BIOS

The basic input/output system (BIOS) resides in ROM on the system board and provides device-level control for the major I/O devices in the system. Additional ROM modules may be located on option adapters to provide device level control for that option adapter. BIOS routines enable the assembly-language programmer to perform block (diskette) or character-level I/O-operations without concern for device address and operating characteristics. System services, such as time-of-day and memory-size determination, are provided by the BIOS.

The goal is to provide an operational interface to the system and relieve the programmer of the concern about the characteristics of hardware devices. The BIOS interface insulates the user from the hardware, allowing new devices to be added to the system, yet retaining the BIOS-level interface to the device. In this manner, user programs become transparent to hardware modifications and enhancements.

The IBM Personal Computer Macro Assembler manual and the IBM Personal Computer Disk Operating System (DOS) manual provide useful programming information related to this section.

Notes:

BIOS Usage

Access to BIOS is through the software interrupts. Each BIOS entry-point is available through its own interrupt, which can be found in "Personal Computer BIOS Interrupt Vectors", later in this section.

The software interrupts, hex 10 through hex 1A, each access a different BIOS-routine. For example, to determine the amount of memory available in the system,

INT hex 12

invokes the BIOS routine for determining memory size and returns the value to the caller.

All parameters passed to and from the BIOS routines go through the 8088 registers. The prologue of each BIOS function indicates the registers used on the call and the return. For the memory size example, no parameters are passed. The memory size, in 1K byte increments, is returned in the AX register.

If a BIOS function has several possible operations, the AH register is used at input to indicate the desired operation. For example, to set the time-of-day, the following code is required:

MOV AH,1 ;function is to set time-of-day.

MOV CX,HIGH_COUNT ;establish the current

MOV DX,LOW_COUNT
INT 1AH ;set the time.

To read time-of-day:

MOV AH,0 ; function is to read time of day.

INT 1AH ; read the timer.

Generally, the BIOS routines save all registers except for AX and the flags. Other registers are modified on return, only if they are returning a value to the caller. The exact register usage can be seen in the prologue of each BIOS function.

Personal Computer BIOS Interrupt Vectors

Vectors with Special Meanings

The following are vectors with special meanings.

Interrupt Hex 1B - Keyboard Break Address

This vector points to the code to be executed when **Break** is pressed on the keyboard. The vector is invoked while responding to the keyboard interrupt, and control should be returned through an IRET instruction. The POWER-ON routines initialize this vector to an IRET instruction, so that nothing occurs when **Break** is pressed unless the application program sets a different value.

Control may be retained by this routine, with the following problem. The 'Break' may have occurred during interrupt processing, so that one or more 'End of Interrupt' commands must be issued in case an operation was underway at that time.

Interrupt Hex 1C - Timer Tick

This vector points to the code to be executed on every system-clock tick. This vector is invoked while responding to the 'timer' interrupt, and control should be returned through an IRET instruction. The POWER-ON routines initialize this vector to point to an IRET instruction, so that nothing occurs unless the application modifies the pointer. It is the responsibility of the application to save and restore all registers that are modified.

Interrupt Hex 1D - Video Parameters

This vector points to a data region containing the parameters required for the initialization of the 6845 CRT Controller. Note that there are four separate tables, and all four must be reproduced if all modes of operation are to be supported. The POWER-ON routines initialize this vector to point to the parameters contained in the ROM video-routines. It is recommended that if a programmer wishes to use a different parameter table, that the table contained in ROM be copied to RAM and just modify the values needed for the application.

Interrupt Hex 1E - Diskette Parameters

This vector points to a data region containing the parameters required for the diskette drive. The POWER-ON routines initialize the vector to point to the parameters contained in the ROM DISKETTE-routine. These default parameters represent the specified values for any IBM drives attached to the machine. Changing this parameter block may be necessary to reflect the specifications of the other drives attached. It is recommended that if a programmer wishes to use a different parameter table, that the table contained in ROM be copied to RAM and just modify the values needed for the application. The motor start-up-time parameter (parameter 10) is overridden by BIOS to force a 500-ms delay (value 04) if the parameter value is less than 04.

Interrupt Hex 1F and hex 44 - Graphics Character Pointers

When operating in the graphics modes, the

read/write-character interface forms the character from the ASCII code-point, using a table of dot patterns where each code point is comprised of 8 bytes of graphics information. The table of dot patterns for the first 128 code-points contained in ROM is pointed to by Interrupt Hex 44 and the second table of 128 code-points contained in ROM is pointed to by Interrupt Hex 1F. The user can change this vector to point to his own table of dot patterns. It is the responsibility of the user to restore these vectors to point to the default code-point-tables at the termination of the program.

Interrupt Hex 48 - Cordless Keyboard Translation

This vector points to the code responsible for translating keyboard scan-codes that are specific to the Cordless Keyboard. The translated scan-codes are then passed to the code pointed to by Interrupt Hex 9 which then handles the 83-key Keyboard scan codes.

Interrupt Hex 49 - Non-Keyboard Scan-Code Translation-Table Address

This interrupt contains the address of a table used to translate non-keyboard scan-codes (scan codes greater than 85 excluding 255.) If Interrupt hex 48 detects a scan code greater than 85 (excluding 255) it translates it using the table pointed to by Interrupt Hex 49. The address that Interrupt Hex 49 points to can be changed by users to point to their own table if different translations are required.

Note: It is recommended that a programmer save default pointers and restore them to their original values when the program has terminated.

Notes:

Other Read Write Memory Usage

The IBM BIOS routines use 256 bytes of memory starting at absolute hex 400 to hex 4FF. Locations hex 400 to 407 contain the base addresses of any RS-232C attachments to the system. This includes the optional IBM PCjr Internal Modem and the standard RS232 serial-port. Locations hex 408 to 40F contain the base addresses of any parallel printer attachments.

Memory locations hex 300 to 3FF are used as a stack area during the power-on initialization, and bootstrap, when control is passed to it from power-on. If the user desires the stack in a different area, the area must be set by the application.

The following is a list of the interrupts reserved for BIOS, DOS, and BASIC.

Address (Hex)	Interrupt (Hex)	Function	
80-83	20	DOS Program Terminate	
84-87	21	DOS Function Call	
88-8B	22	DOS Terminate Address	
8C-8F	23	DOS Ctrl Break Exit Address	
90-93	24	DOS Fatal Error Vector

		BASIC is running	
3C4-3FF	F1-FF	Reserved	

BIOS, BASIC, and DOS Reserved Interrupts

The following is a list of reserved memory locations.

Address (Hex)	Mode	Function
400-48F	ROM BIOS	See BIOS Listing
490-4EF		Reserved for System Usage
500-5FF		Communication Area for any
		application
500	DOS	Reserved for DOS and BASIC,
		Print Screen Status Flag Store,
		O-Print Screen Not Active or
		Successful
		Print Screen Operation,
		1-Print Screen In Progress,
		255-Error Encountered During
		Print
		Screen Operation,
504	DOS	Single Drive Mode Status Byte
510-511	BASIC	BASIC's segment Address Store
512-515	BASIC	Clock Interrupt Vector Segment:
	5.070	Offset Store
516-519	BASIC	Break key Interrupt Vector
51 4 515	DAGIG	Segment: Offset Store
51A-51D	BASIC	Disk Error Interrupt Vector
-		Segment: Offset Store

Reserved Memory Locations

The following is a list of the BASIC workspace variables.

If you do DEF SEG (Default workspace segment):	Offset (Hex)	Length
Line number of current line being executed	2E	2
Line number of last error	347	2
Offset into segment of start of program text	30	2 2
Offset into segment of start of variables (end of program text 1-1)	358	2
Keyboard buffer contents if 0-no characters in buffer if 1-characters in buffer	6A	1
Character color in graphics mode Set to 1, 2, or 3 to get text in colors 1 to 3. Do not set to 0. (Default = 3)	4E	1
Example 100 Print Peek (&H2E) + 256*Peek (&H2E) L H (100 hex 64 hex 00	;)

BIOS Programming Guidelines

The BIOS code is invoked through software interrupts. The programmer should not 'hard code' BIOS addresses into applications. The internal workings and absolute addresses within BIOS are subject to change without notice.

If an error is reported by the diskette code, you should 'reset' the drive adapter and retry the operation. A specified number of retries should be required on diskette 'reads' to insure the problem is not due to motor start-up.

When altering I/O-port bit-values, the programmer should change only those bits which are necessary to the current task. Upon completion, the programmer should restore the original environment. Failure to adhere to this practice may be incompatible with present and future systems.

Adapter Cards with System-Accessible ROM-Modules

The ROM BIOS provides a facility to integrate adapter cards with on-board ROM-code into the system. During the Power-On Self-Test (POST), interrupt vectors are established for the BIOS calls. After the default vectors are in place, a scan for additional ROM modules takes place. At this point, a ROM routine on the adapter card may gain control. The routine may establish or intercept interrupt vectors to hook themselves into the system.

The absolute addresses hex C0000 through hex D0000 are scanned in 2K-byte blocks in search of a valid adapter card ROM. A valid ROM is defined as follows:

Byte 0: hex 55

Byte 1: hex AA

Byte 2: length (multiple of 2K bytes) - A length indicator representing the number of

512-byte blocks in the ROM

(length/512). A checksum is also done to test the integrity of the ROM module. Each byte in the defined ROM is summed modulo hex 100. This sum must be 0 for

the module to be deemed valid.

When the POST identifies a valid ROM, it does a 'far call' to byte 3 of the ROM (which should be executable code). The adapter card may now perform its power-on initialization-tasks. The feature ROM should return control to the BIOS routines by executing a 'far return'.

Notes:

Keyboard Encoding and Usage

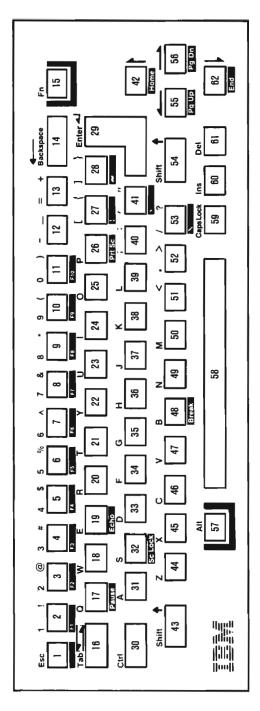

The following explains how the keyboard interacts with BIOS and how 83-key-keyboard functions are accomplished on the Cordless Keyboard.

Cordless Keyboard Encoding

The KEYBOARD routine provided by IBM in the ROM BIOS is responsible for converting the keyboard scan-codes into what is termed "Extended ASCII."

Extended ASCII encompasses one-byte character-codes with possible values of 0 to 255, an extended code for certain extended keyboard-functions, and functions handled within the KEYBOARD routine or through interrupts.

The following is the physical layout of the IBM PCjr Cordless Keyboard.

IBM PCjr Cordless Keyboard Diagram

The following are charts of the scan codes for the IBM PCjr Cordless Keyboard.

Key Position	Keyboard Characters	Make Code (Hex)	Break Code (Hex)
1	ESC	1	81

Cordless-Keyboard Character Codes (Part 4 of 4)

Extended Codes

An extended code is used for certain functions that cannot be represented in the standard ASCII code. A character code of 000 (Nul) is returned in AL. This indicates that the system or application program should examine a second code that indicates the actual function. This code is returned in AH. This is the same for both the Cordless Keyboard and 83-key keyboard.

	Second Code	Function	
	3	Null Character	
	15	—	
$\overline{}$	16 through 25	Alt Q, W, E, R, T, Y, U, I, O, P	
	30 through 38	Alt A, S, D, F, G, H, J, K, L	
	44 through 50	Alt Z, X, C, V, B, N, M	
	59 through 68	Fn + 1, 2, 3, 4, 5, 6, 7, 8, 9, 0 (Functions 1	
		through 10)	
	71	Home	
	72	Up Arrow	
	73	Page Up	
	75	(Cursor Left)	
	77	(Cursor Right)	
	79	End	
	80	Down Arrow	
	81	Page Down	
	82	Ins (Insert)	
	83	Del (Delete)	
	84 through 93	F11 through F20 (Upper Case F1	
		through F10)	
	94 through 103	F21 through F30 (Ctrl F1 through F10)	
	104 through 113	F31 through F40 (Alt F1 through F10)	
	114	Fn/E or Ctrl/Fn/P (Start/Stop Echo to	
	-	Printer)	
	115	Ctrl (Reverse Word)	
1	116	Ctrl (Advance Word)	
	117	Ctrl/End [Erase End of Line (EOL)]	
	118	Ctrl/PgDn [Erase to End of Screen (EOS)]	
	119	Ctrl/Home (Clear Screen and Home)	
	120 through 131	Alt/1, 2, 3, 4, 5, 6, 7, 8, 9, 0, -, = (Keys 2	
	1.22	through 13)	
	132	Ctrl/PgUp (Top 25 Lines of Text and	
		Home Cur.)	
	133 through 149	Reserved	
	150 through 190	Reserved for Non-Keyboard Scan Codes	

Cordless Keyboard Extended Functions

Shift States

Most shift states are handled within the KEYBOARD routine, transparent to the system or application

program. The current set of active shift states is available by 'calling' an entry point in the ROM KEYBOARD-routine. The following keys result in altered shift-states:

Shift

This key temporarily shifts keys 2 thru 13, 16 thru 28, 31 thru 41, and 44 thru 53 to upper case (base case if in Caps Lock state). The Shift key temporarily reverses the 'Num Lock' or 'non-Num-Lock' state of keys 42, 55, 56, and 60 thru 62.

Ctrl

This key temporarily shifts keys 3, 7, 12, 14, 16 thru 28, 30 thru 38, 42, 44 thru 50, 55, and 56 to the Ctrl state. The Ctrl key is used with the Alt and Del keys to cause the 'System Reset' function, with the Scroll Lock key to cause the 'Break' function, with the Num Lock key to cause the 'Pause' function, with the Alt and Cursor Left or Right for 'screen adjustment', with Alt and Ins to 'activate diagnostics', and with Alt and CapsLock to 'activate keyboard clicking'. These functions are described in "Special Handling" on the following pages.

Alt

The Alt key temporarily shifts keys 2 thru 13, 17 thru 26, 31 thru 39, and 44 thru 50 to the 'Alternate state'. The Alt key is used with the Ctrl and Del keys to cause the 'System Reset' function described in "Special Handling" on the following pages. The Alt key is also used with keys 27, 28, 41, and 53 to produce the characters under the key.

The Alt key has another use. This key allows the user to enter any character code from 0 to 255 into the system from the keyboard. The user must first put the keyboard in the 'Num Lock' state (concurrently press, first Alt then Fn + n). Then while holding down the Alt key type the decimal value of the character desired using keys 2 thru 11. The Alt key is then released. If more than three digits are typed, a modulo-256 result is created. These three digits are interpreted as a character code and are transmitted through the KEYBOARD routine to the system or application program. Alt is handled internal to the KEYBOARD routine

Caps Lock

This key shifts keys 17 thru 25, 31 thru 39, and 44 thru 50 to 'upper case'. A second press of the Caps Lock key reverses the action. Caps Lock is handled internal to the KEYBOARD routine.

Shift-Key Priorities and Combinations

The following keys are listed in descending priority for translation in Interrupt Hex 48 and Interrupt hex 9 respectively:

- 1. Interrupt Hex 48
 - a. Alt key
 - b. Ctrl key
 - c. Shift key
- 2. Interrupt Hex 9
 - a. Ctrl
 - b. Alt
 - c. Shift

Of the three keys listed, only Alt and Ctrl are a valid combination. If any other combination of the three keys is used, only the key with the higher priority is recognized by the system.

Special Handling

System Reset

The combination of the Alt, Ctrl, and Del keys causes the KEYBOARD routine to initiate the equivalent of a 'System Reset'.

Break

The combination of the Fn and B keys results in the KEYBOARD routine signaling Interrupt Hex 1A. The extended characters (AL = hex 00, AH = hex 00) are returned.

Pause

The combination of the Fn and Q keys causes the KEYBOARD-interrupt routine to loop, waiting for any key to be pressed. This provides a system or application-transparent method of temporarily suspending an operation such as list or print and then resuming the operation by pressing any other key. The key pressed to exit the 'Pause' mode is unused otherwise.

Print Screen

The combination of the Fn and P keys results in an interrupt, invoking the PRINT SCREEN routine. This

routine works in the alphanumeric or graphics mode, with unrecognizable characters printing as blanks.

Scroll Lock

The combination of the Fn and S key is interpreted by appropriate application programs to indicate that the cursor-control keys should cause 'windowing' over the text rather than cursor movement. Pressing the 'Scroll Lock' combination a second time reverses the action. The KEYBOARD routine simply records the current shift state of 'Scroll Lock'. It is the responsibility of the system or application program to perform the function.

Functions 1 thru 10

The combination of the Fn key (15) and one of keys 2 thru 11 results in the corresponding 'Function' with key 2 being 'F1' up to key 11 being 'F10'.

Function Lock

Concurrently pressing first the Fn key and Shift key, and then pressing the Esc key causes keys 2 thru 11 to shift to their 'Function' states and remain there until the same combination is pressed again.

Screen Adjustment

The combination of the Alt key, Ctrl key, and either the Left or Right cursor movement key causes the screen to shift one character in the corresponding direction, up to a maximum of four.

Enable/Disable Keyboard Click

The combination of the Alt, Ctrl, and Caps Lock keys causes the keyboard audio feedback (click) to shift between 'on' and 'off'. The Power-On default is 'off'.

Run Diagnostics

The combination of the Alt, Ctrl, and Ins keys causes the system diagnostics stored in ROM to be initiated.

Phantom-Key Scan-Code (Hex 55)

The Phantom-Key scan-code is generated by the keyboard when an invalid combination of three or more keys is pressed. The keys pressed that caused the Phantom-Key scan-code are not put into the keyboard buffer, and are ignored by the keyboard microprocessor. The Phantom-Key scan-code is transmitted to BIOS where it is ignored.

Other Characteristics

The keyboard buffer is large enough to support a fast typist. If a key is pressed when the buffer is full, the character generated is ignored and the 'bell' is sounded. A larger buffer can be specified by modifying words at labels 'Buffer-Start' (hex 480) and 'Buffer-End' (hex 482) to point to another offset within segment hex 40.

The KEYBOARD routine suppresses the typematic action of the following keys: Ctrl, Shift, Alt, Caps Lock, Insert, and Function.

	Function	Key Combinations	Description
	System Reset	Alt + Ctrl + Del	Unconditional system reset
)	Break	Fn + B	Breaks program execution
	Pause	Fn + Q	Resumable pause in program execution
	Print Screen	Fn + P	
	Function Lock	Fn and Shift then Esc (Held) concurrently)	Locks the number keys as Function keys (F1-F10) and B, Q, P, E, S, and the cursor control keys to their function states
	Screen Adjustment	Alt + Ctrl + cursor right or cursor left	Allows the user to adjust the display's image left or right
)	Keyboard Click	Alt + Ctrl + CapsLock	Enables or disables the keyboard audio feedback click
	Run Diagnostics	Alt + Ctrl + Ins	Initiates system ROM diagnostics
	Keyboard Adventure Game	Esc	If the first key pressed after the system comes up in Cassette BASIC is Esc (key #1) then the Keyboard Adventure Game will be activated.
	Cassette Autoload	Ctrl + Esc	If this is the first key sequence after the system comes up in Cassette BASIC then the screen will display 'Load "CASI:", R followed by a Carriage Return. This allows a cassette program to be automatically loaded.

Keyboard Usage

"Keyboard Usage" is a set of guidelines of key-usage when performing commonly-used functions.

Function	Keys	Comment
Home Cursor	Fn Home	Editors; word processors
Return to outermost menu	Fn Home	Menu driven applications
Move cursor up	Up Arrow	Full screen editor, word processor
Page up, scroll backwards 25 lines	Fn PgUp	Editors; word processors
Move cursor left	4	Text, command entry
Move cursor right		Text, command entry
Scroll to end of text place cursor at end of line	Fn End	Editors; word processors
Move cursor down	Down Arrow	Full screen editor, word processor
Page down, scroll forwards 25 lines and home	Fn PgDn	Editors; word processors
Start/Stop insert text at cursor, shift text right in buffer	Ins	Text, command entry

Keyboard - Commonly Used Functions (Part 1 of 3)

Function	Keys	Comment
Delete character at cursor	Del	Text, command entry
Destructive backspace	← Key 14	Text, command entry
Tab forward	·	Text entry
Tab reverse		Text entry
Clear screen and home	Ctrl Fn Home	
Scroll up	Up Arrow	In scroll lock mode
Scroll down	Down Arrow	In scroll lock mode
Scroll left	4	In scroll lock mode
Scroll right		In scroll lock mode
Delete from cursor to EOL (end of line)	Ctrl Fn End	Text, command entry
Exit/Escape	Esc	Editor, I level of menu and so on
Start/Stop Echo screen to printer	Fn PrtSc	Any time
Delete from cursor to EOS (end of screen)	Ctrl Fn PgDn	Text, command entry
Advance word	Ctrl —	Text entry
Reverse word	Ctrl —	Text entry
Window Right	Ctrl —	When text is too wide to fit the screen

Keyboard - Commonly Used Functions (Part 2 of 3)

Function	Keys	Comment
Window Left	Ctrl —	When text is too wide to fit the screen
Enter insert mode	Ins	Line Editor
Exit insert mode	Ins	Line Editor
Cancel current line	Esc	Command entry, text entry
Suspend system (Pause)	Ctrl Fn Pause	Stop list, stop program, and so on. Resumes on any key.
Break interrupt	Fn Break	Interrupt current process
System reset	Alt Ctrl Del	Reboot
Top of document and home cursor	Ctrl Fn PgUp	Editors, word processors
Standard function keys	Shift Fn/F1 through Fn/F10	Primary function keys
Secondary function keys	Shift F1-F10 Ctrl F1-F10 Alt F1-F10	Extra function keys if 10 are not sufficient.
Extra function keys	Alt keys 2 through 13 (1 through 9, 0) (-, =)	Line Editor
Extra function keys	Alt A through Z	Used when function starts with the same letter as one of the alpha keys.

Keyboard - Commonly Used Functions (Part 3 of 3)

5-40 Keyboard Encoding

Function	Key
Carriage return	▲ (Enter)
Line feed	Ctrl 📣 (Enter)
Bell	Ctrl G
Home	Fn Home
Cursor up	Up Arrow
Cursor down	Down Arrow
Cursor left	4-
Cursor right	
Advance one word	Ctrl —
Reverse one word	Ctrl —
Insert	Ins
Delete	Del
Clear screen	Ctrl Fn Home
Freeze output	Fn Pause
Tab advance	<u> </u>
Stop Execution (break)	Fn Break
Delete current line	Esc
Delete to end of line	Ctrl Fn End
Position cursor to end of line	Fn End

BASIC Screen Editor Special Functions

Function	Key
Suspend	Fn Pause
Echo to printer	Fn Echo
Stop echo to printer	Fn Echo
Exit current function (break)	Fn Break
Backspace	← Key 14
Line feed	Ctrl 🗚 (Enter)
Cancel line	Esc
Copy character	Fn F1 or —
Copy until match	Fn F2
Copy remaining	Fn F3
Skip character	Del
Skip until match	Fn F4
Enter insert mode	Ins
Exit insert mode	Ins
Make new line the template	Fn F5
String separator in REPLACE	Fn F6
End of file in keyboard input	Fn F6

DOS Special Functions

Non-Keyboard Scan-code Architecture

The architecture of the IBM PCjr BIOS is designed to also receive scan codes above those generated by the keyboard to accommodate any future device.

The keyboard generates scan codes from hex 1 to 55 and FF. Any scan codes above hex 55 (56 thru 7E for 'make' codes and D6 thru FE for 'break' codes) are processed by BIOS in the following manner:

 If the incoming 'make' scan code falls within the range of the translate table, whose address is pointed to by BIOS Interrupt Hex 49, it is translated into the corresponding scan code. Any incoming 'break' codes above hex D5 are ignored.

- If the new translated scan code is less than hex 56, it is processed by BIOS as a keyboard scan-code and the same data is placed in the BIOS keyboard buffer.
- 3. If the translated scan-code is greater than hex 55 or the incoming scan-code is outside the range of the translate table, hex 40 is added, creating a new extended-scan-code. The new extended-scan-code is then placed in the BIOS keyboard buffer with the character code of 00(null). This utilizes the range hex 96 thru BE for scan codes hex 56 thru 7E respectively.

The default translate-table maps scan codes hex 56 thru 6A to existing keyboard-values. Scan codes hex 6B thru BE are mapped (by adding hex 40) to extended codes of hex AB thru FE, since these are out side the range of the default translate-table.

Users can modify Interrupt Hex 49 to address their own translate table if mapping differences are desired.

The translate table format is:

Description

- Length The number of non-keyboard scan-codes that are mapped within the table (from 1 to n).
- 1 to n Word with low-order byte representing the scan-code-mapped values relative to the input values in the range of hex 56 thru 7E.

	8-Bits							
	Length = 1 to n							
,	High Byte - 0 (NUL)							
1	Low Byte - Scan Code							
	High Byte - 0 (NUL)							
2	Low Byte - Scan Code							
2	High Byte - 0 (NUL)							
3	Low Byte - Scan Code							
	•							
•	•							
	•							
	•							
	High Byte - 0 (NUL)							
n	Low Byte - Scan Code							

Translate Table Format

With this architecture, all keyboard scan-codes can be intercepted thru Interrupt Hex 9 and all non-keyboard scan-codes can be intercepted thru Interrupt Hex 48.

The following is a chart showing the default values of the translate table in BIOS.

Length = 20 mapped values											
	Mapped Value	Keyboard Character									
86	72	(cursor up)									
87	73	PgUp									
88	77	(cursor right)									
89	81	PgDn									
90	80	(cursor down)									
91	79	End									
92	75	(cursor left)									
93	71	Home									
94	57	Space									
95	28	Enter									
96	17	W									
97	18	E									
98	31	S									
99	45	X									
100	44	Z									
101	43	\									
102	30	A									
103	16	Q									
104	15	Tab									
105	1	Esc									

Translate Table Default Values

Scan Codes (Hex)	Type of Scan Code
1 - 55	Normal Keyboard Scan Code (Make)
56 - 7E	Non-Keyboard Scan Code (Make)
81 - D5	Normal Keyboard Scan Code (Break)
D6 - FE	Non-Keyboard Scan Code (Break)
FF	Keyboard Buffer Full

Scan-Code Map

Notes:

BIOS Cassette Logic

Software Algorithms - Interrupt Hex 15

The CASSETTE routine is called by the request type in AH. The address of the bytes to be 'read' from or 'written' to the tape is specified by DS:BX and the number of bytes to be 'read' or 'written' is specified by CX. The actual number of bytes 'read' is returned in DX. The read block and write block automatically turn the cassette motor on at the start and off at the end. The request types in AH and the cassette status descriptions follow:

Request Type	Function
AH = 0 AH = 1 AH = 2	Turn Cassette Motor On Turn Cassette Motor Off Read Tape Block Read CX bytes into memory starting at Address DS:BX Return actual number of bytes read in DX Return Cassette Status in AH
AH = 3	Write Tape Block Write CX bytes onto cassette starting at Address DS:BX Return Cassette Status in AH

AH Request Types

Cassette Status	Description						
AH = 00	No Errors						
AH = 01	Cyclic Redundancy Check (CRC) Error in						
	Read Block						
AH = 02	No Data Transitions						
AH = 04	No Leader						
AH = 80	Invalid Command						
Note: The carry flag will be set on any error.							

AH Cassette Status

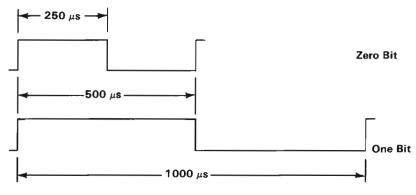

Cassette Write

The WRITE-BLOCK routine 'writes' a tape block onto the cassette tape. The tape block is described in "Data Record Architecture" later in this section.

The WRITE-BLOCK routine 'turns on' the cassette drive motor and 'writes' the leader (256 bytes of all 1's) to the tape, 'writes' a synchronization bit (0), and then 'writes' a synchronization byte (ASCII character hex 16). Next, the routine 'writes' the number of data bytes specified by CX. After each data block of 256 bytes, a 2-byte cyclic redundancy check (CRC) is 'written'. The data bytes are taken from the memory location 'pointed' at by DS:BX.

The WRITE-BLOCK routine 'disassembles' and 'writes' the byte a bit-at-a-time to the cassette. The method used is to 'set' Timer 2 to the period of the desired data bit. The timer is 'set' to a period of 1.0 millisecond for a 1 bit and 0.5 millisecond for a 0 bit.

The timer is 'set' to mode 3, which means the timer outputs a square wave with a period given by its count register. The timer's period is changed on the fly for each data byte 'written' to the cassette. If the number of data bytes to be 'written' is not an integral multiple of 256, then, after the last desired data byte from memory has been 'written', the data block is extended to 256 bytes of writing multiples of the last data byte. The last block is closed with two CRC bytes as usual. After the last data-block, a trailer consisting of four bytes of all 1 bits is 'written'. Finally, the cassette motor is 'turned off', if there are no errors reported by the routine. All 8259 interrupts are 'disabled' during cassette-write operations.

Cassette-Write Timing Chart

Cassette Read

The READ-BLOCK routine 'turns on' the cassette drive motor and then delays for approximately 0.5 second to allow the motor to come up to speed.

The READ-BLOCK routine then searches for the leader and must detect all 1 bits for approximately 1/4 of the leader length before it can look for the sync (0) bit. After the sync bit is detected, the sync byte

(ASCII character hex 16) is 'read'. If the sync byte is 'read' correctly, the data portion can be 'read'. If a correct sync byte is not found, the routine goes back and searches for the leader again. The data is 'read' a bit-at-a-time and 'assembled' into bytes. After each byte is 'assembled', it is 'written' into memory at location DS:BX and BX is incremented by 1.

After each multiple of 256 data bytes is 'read', the CRC is 'read' and 'compared' to the CRC generated. If a CRC error is detected, the routine exits with the carry flag 'set' to indicate an error and the status of AH 'set' to hex 01. DX contains the number of bytes 'written' into memory.

All 8259 interrupts are 'disabled' during the cassette-'read' operations.

Data Record Architecture

The WRITE-BLOCK routine uses the following format to record a tape block onto a cassette tape:

(CASSETTE TAPE BLOCK)

Leader	Sync Bit	Sync Byte	Data Block	CRC	Data Block	CRC
Motor On						Motor Off

Cassette Write-Block Format

Component	Description
Leader Sync Bit Sync Byte Data Blocks CRC	256 Bytes (of All 1's) One 0 bit ASCII Character hex 16 256 Bytes in Length 2 Bytes for each Data Block

Data Record Components

Error Detection

used to detect errors. The polynomial used is $G(X) = X^{16} + X^{12} + X^5 + 1$, which is the polynomial used by the synchronous data link control interface. Essentially, as bits are 'written' to or 'read' from the cassette tape they are passed through the CRC register in software. After a block of data is 'written', the complemented value of the calculated CRC register is 'written' on the tape. Upon reading the cassette data, the CRC bytes are 'read' and 'compared' to the generated CRC value. If the read CRC does not equal the generated CRC, the processor's carry flag is 'set' and the status of AH is 'set' to hex 01, which indicates a CRC error has occurred. Also, the routine is exited on a CRC error.

Error detection is handled through software. A CRC is

THE BURST OF TYPAMATIC CHARS.

(AL)=2 HALF_RATE. SLOWS TYPAMATIC CHARACTERS
BY ONE HALF.

(AL)=3 COMBINES AL=1 AND AL=2. INCREASES
                                                                                                                       COMBINES AL=1 ANO AL=2. INCREASES
INITIAL DELAY ANO SLOMS TYPAMATIC
CHARACTERS BY ONE-HALF,
TURN OFF TYPAMATIC CHARACTERS. ONLY THI
FIRST CHARACTER IS HONORED. ALL OTHERS
                                                                                                 (AL)=3
                                                                                                                                                                                        ONLY THE
                                                                                                 (AL)=4
                                                                                                 ARE IGNORED.

AL IS RANGE CHECKED. IF AL<0 OR AL>4 THE STATE
REMAINS THE SAME.
                                                                                                REMAINS THE SAME.

##MOTEM## EACH TIME THE TYPAMATIC RATES ARE
CHANGED ALL PREVIOUS STATES ARE REMOVED. I.E. IF
THE KEYBOARD IS IN THE HALF RATE MODE AND YOU MANT
TO ADD AN INCREASE IN TYPAMATIC DELAY, YOU MUST
CALL THIS ROUTINE WITH AH=3 AND AL=3.

ADJUST KEYBOARD BY THE VALUE IN AL AS FOLLOWS:
                                                                                                (AL)=0 TURN OFF KEYBOARD CLICK.
(AL)=1 TURN ON KEYBOARD CLICK.
AL IS RANGE CHECKED. THE STATE IS UNALTERED IF
AL ($1,0.
                                                                                 (AH)=4

THIS INTERFACE PROVIDES A TELETYPE-LIKE INTERFACE TO THE VIDEO CARD. THE INPUT CHARACTER IS WRITTEN TO THE CURRENT CURSOR POSITION, AND THE CURSOR IS MOVED TO THE NEXT POSITION. IF THE CURSOR LEAVES THE LAST COLUMN OF THE FIELD, THE COLUMN IS SET TO ZERO, AND THE ROW VALUE IS INCREMENTED. IF THE ROW ROW VALUE LEAVES THE FIELD, THE CURSOR IS PLACED ON THE LAST ROW, FIRST COLUMN, AND THE ENTIRE SCREEN IS SCROLLED UP ONE LIME. WHEN THE SCREEN IS SCROLLED UP, THE ATTRIBUTE FOR FILLING THE NEWLY BLANKED LINE IS SCROLLED UP, THE ATTRIBUTE FOR FILLING THE NEWLY BLANKED LINE IS READ FROM THE CURSOR POSITION ON THE PREVIOUS LINE BEFORE THE SCROLL, IN CHARACTER MODE. IN GRAPHICS MODE, THE O COLOR IS USED.
                                                                                                                                 THE ATTRIBUTE FOR FILLING

   TRANSHITTER HOLDING REGISTER EMPTY INTERRUPT TEST
THIS TEST HAS BEEN MODIFIED BECAUSE THE DIFFERENT B250'S
THAT HAY BE USED IM PRODUCING THIS PRODUCT 00 MOT FUNCTION
THE SAME DURING THE STANDARD TEST OF THIS INTERRUPT
(STANDARD BEING THE SAME METHOD FOR TESTING THE OTHER
             POSSIBLE B250 INTERRUPTS) IT IS STILL VALID FOR TESTING
IF AN 8259 INTERRUPT IS GENERATED IN RESPONSE TO THE 8250
INTERRUPT AND THAT THE 8250 INTERRUPT CLEARS AS IT SHOULD.
             IF THE TRANSMITTER HOLDING REGISTER EMPTY INTERRUPT IS NOT GENERATED WHEN THAT INTERRUPT IS SHABLED, IT IS NOT TREATED AS AN ERROR. HOWEVER, IF THE INTERRUPT IS GENERATED, IT WUST GENERATE AN 8259 INTERRUPT AND CLEAR PROPERLY TO PASS THIS TEST.

THIS ROUTINE HANDLES THE DISKETTE INTERRUPT. AN INTERRUPT
WILL OCCUR ONLY WHEN THE ONE-SHOT TIMER IS FIRED. THIS
OCCURS IN AN ERROR SITUATION. THIS ROUTINE SETS ERRORS IN
THE DISKETTE STATUS BYTE AND DISABLES THE ONE-SHOT TIMER.
THEN THE RETURN ADDRESS ON THE STACK IS CHANGED TO RETURN
TO THE OP_END LABEL.

                 AL, DX
        RET
```

THIS ROUTINE HANDLES THE TIMER INTERRUPT FROM CHANNEL O OF THE 8283 THER. INPUT FREQUENCY IS 1.19318 MHZ AND THE DIVISOR IS 65536, RESULTING IN APPROX. 18.2 INTERRUPTS EVERY SECOND.

THE INTERRUPT HANDLER MAINTAINS A COUNT OF INTERRUPTS SINCE POWER ON TIME, WHICH MAY BE USED TO ESTABLISH TIME OF DAY. INTERRUPTS MISSED WHILE INTS. WERE DISABLED ARE TAKEN CARE OF BY THE USE OF TIMER I AS A OVERFLOW COUNTER CONTROL COUNT OF THE DISKETTE, AND WHEN IT EXPIRES, WILL TURN OFF THE DISKETTE NOTOR, AND RESET THE MOTOR RUNNING FLAGS
THE INTERRUPT HANDLER WILL ALSO INVOKE A USER ROUTIME THROUGH INTERRUPT LOCATE WITH THE TICK. THE USER MUST CODE A ROUTINE AND PLACE THE CORRECT ADDRESS IN THE VECTOR TABLE.

AND PLACE THE CORRECT ADDRESS IN THE VECTOR TABLE. ORG OFEASH

FE	254	: 🔳	Alt 254	Note 6	White	Yellow		
FF	255	BLANK	Alt 255	Note 6	White	White		

NOTE 1	On the 62-key keyboard the Asterisk (*) can be keyed using two methods:
	1) in the shift mode hit the $\begin{bmatrix} * \\ 8 \end{bmatrix}$ key or 2) hold Alt key and press the
	key.

On the 83-key keyboard the Asterisk (*) can be keyed using two methods:

1) hit the Prt Sc key or 2) in the shift mode hit the key.

- NOTE 2 Period (.) can easily be keyed using two methods: 1) hit the key or 2) in shift or Num Lock mode hit the bell key.
- NOTE 3 Numeric characters (0—9) can easily be keyed using two methods: 1) hit the numeric keys on the top row of the typewriter portion of the keyboard or 2) on the 83-key keyboard in shift or Num Lock mode hit the numeric keys in the 10—key pad portion of the keyboard.
- NOTE 4 Upper case alphabetic characters (A—Z) can easily be keyed in two modes:
 1) in shift mode the appropriate alphabetic key or 2) In Caps Lock mode hit the appropriate alphabetic key.
- NOTE 5 Lower case alphabetic characters (a—z) can easily be keyed in two modes:

 1) in "normal" mode hit the appropriate key or 2) In Caps Lock combined with shift mode hit the appropriate alphabetic key.
- NOTE 6 On the 62-key keyboard set Num Lock state using Alt/Fn/N then 3 digits after the Alt key must be typed from the numeric keys on the top row of the typematic portion of the keyboard. Character codes 000 through 255 can be entered in this fashion. (With Caps Lock activated, character codes 97 through 122 will display upper case rather than lower case alphabetic characters.)

On the 83-key keyboard the 3 digits after the Alt key must be typed from the numeric key pad (keys 71—73, 75—77, 79—82).

Appendix D. UNIT SPECIFICATIONS

System Unit

Size:

Length 354 mm (13.9 in.)

Depth 290 mm (11.4 in.)

Height 97 mm (3.8 in.)

Weight:

3.71 Kg (8lb 4oz) With Diskette Drive
2.61 Kg (5lb 8oz) Without Diskette Drive

Transformer:

Electrical:

Input 110 Vac 60 Hz

Output to System Pin 1 - 17 Vac, Pin 2 - GND, Pin 3 -

17 Vac

Power Cords:

Input Length 1.86 meters (6.14 feet)

Type 18 AWG

Output Length 1.22 meters (4.02 feet)

Type 18 AWG

Environment:

Air Temperature

System ON 15.6 to 32.2 degrees C (60 to 90 degrees F)

System Off 10 to 43 degrees C (50 to 110 degrees F)

Humidity

System On 8% to 80% System Off 8% to 80%

Noise Level 45 dB

Cordless Keyboard

Size:

Length 341.5 mm (13.45 in.) **Depth** 168 mm (6.61 in.)

Height 26 mm (1.02 in.)

Weight:

With Batteries 616 grams (22 ounces)
Without Batteries 700 grams (25 ounces)

Optional Cable:

6 feet, flat

Diskette Drive

Glossary

μs Microsecond.

adapter. An auxiliary system or unit used to extend the operation of another system.

address bus. One or more conductors used to carry the binary-coded address from the microprocessor throughout the rest of the system.

all points addressable (APA). A mode in which all points on a displayable image can be controlled by the user.

alphanumeric

(A/N). Pertaining to a character set that contains letters, digits, and usually other characters, such as punctuation marks. Synonymous with alphameric.

American Standard Code for Information Interchange. (ASCII) The standard code, using a coded character set consisting of 7-bit coded characters (8 bits

including parity check), used for information interchange among data processing systems, data communication systems and associated equipment. The ASCII set consists of control characters and graphic characters.

A/N. Alphanumeric.

analog. (1) pertaining to data in the form of continuously variable physical quantities.(2) Contrast with digital.

AND. A logic operator having the property that if P is a statement, Q is a statement, R is a statement,..., then the AND of P, Q, R,...is true if all statements are true, false if any statement is false.

APA. All points addressable.

ASCII. American Standard Code for Information Interchange.

assembler. A computer program used to assemble. Synonymous with assembly program.

asynchronous communications. A communication mode in which each single byte of data is synchronized, usually by the addition of start/stop bits.

BASIC. Beginner's all-purpose symbolic instruction code.

basic input/output system (BIOS). Provides the device level control of the major I/O devices in a computer system, which provides an operational interface to the system and relieves the programmer from concern over hardware device characteristics.

baud. (1) A unit of signaling speed equal to the number of discrete conditions or signal events per second. For example, one baud equals one-half dot cycle per second in Morse code, one bit per second in a train of binary signals, and one 3-bit value per second in a train of signals each of which can assume one of eight different states. (2) In

asynchronous transmission, the unit of modulation rate corresponding to one unit of interval per second; that is, if the duration of the unit interval is 20 milliseconds, the modulation rate is 50 baud.

BCC. Block-check character.

beginner's all-purpose symbolic instruction. code (BASIC) A programming language with a small repertoire of commands and a simple syntax, primarily designed for numerical application.

binary. (1) Pertaining to a selection, choice, or condition that has two possible values or states. (2) Pertaining to a fixed radix numeration system having a radix of two.

binary digit. (1) In binary notation, either of the characters 0 or 1. (2) Synonymous with bit. binary notation: Any notation that uses two different characters, usually the binary digits 0 and 1.

BIOS. Basic input/output system.

bit. In binary notation, either of the characters 0 or 1.

bits per second (bps). A unit of measurement representing the number of discrete binary digits which can be transmitted by a device in one second.

block-check character (BCC). In cyclic redundancy checking, a character that is transmitted by the sender after each message block and is compared with a block-check character computed by the receiver to determine if the transmission was successful.

Boolean operation. (1) Any operation in which each of the operands and the result take one of two values. (2) An operation that follows the rules of Boolean algebra.

bootstrap. A technique or device designed to bring itself into a desired state by means of its own action; that is, a machine routine whose first few instructions are sufficient to bring the rest of itself into the computer from an input device.

bps. Bits per second.

buffer. (1) An area of storage that is temporarily reserved for use in performing an input/output operation, into which data is read or from which data is written.

Synonymous with I/O area.

(2) A portion of storage for temporarily holding input or output data.

bus. One or more conductors used for transmitting signals or power.

byte. (1) A binary character operated upon as a unit and usually shorter than a computer word. (2) The representation of a character.

CAS. Column address strobe.

cathode ray tube (CRT). A vacuum tube display in which a beam of electrons can be controlled to form alphanumeric characters or symbols on a luminescent screen, for example by use of a dot matrix.

cathode ray tube display (CRT display). (1) A device that presents data in visual form by means of controlled electron

beams. (2) The data display produced by the device as in (1).

CCITT. Comite Consultatif International Telegrafique et Telephonique.

central processing unit (CPU). A functional unit that consists of one or more processors and all or part of internal storage.

channel. A path along which signals can be sent; for example, data channel or I/O channel.

characters per second (cps). A standard unit of measurement for printer output.

code. (1) A set of unambiguous rules specifying the manner in which data may be represented in a discrete form.

Synonymous with coding scheme. (2) A set of items, such as abbreviations, representing the members of another set. (3) Loosely, one or more computer programs, or part of a computer program.

(4) To represent data or a

computer program in a symbolic form that can be accepted by a data processor.

column address strobe(CAS). A signal that latches the column addresses in a memory chip.

Comite Consultatif
International. Telegrafique et
Teleponique (CCITT)
Consultative Committee on
International Telegraphy and
Telephone.

computer. A functional unit that can perform substantial computation, including numerous arithmetic operations, or logic operations, without intervention by a human operator during the run.

configuration. (1) The arrangement of a computer system or network as defined by the nature, number, and the chief characteristics of its functional units. More specifically, the term configuration may refer to a hardware configuration or a software configuration. (2) The devices and programs that make up a system, subsystem, or network.

conjunction. (1) The Boolean operation whose result has the Boolean value 1 if, and only if, each operand has the Boolean value 1. (2) Synonymous with AND operation.

contiguous. (1) Touching or joining at the edge or boundary. (2) Adjacent.

CPS. Characters per second.

CPU. Central processing unit.

CRC. Cyclic redundancy check.

CRT display. Cathode ray tube display.

CTS. Clear to send.
Associated with modem control.

cyclic redundancy check
(CRC). (1) A redundancy
check in which the check key is
generated by a cyclic algorithm.
(2) A system of error checking
performed at both the sending
and receiving station after a
block-check character has been
accumulated.

cylinder. (1) The set of all tracks with the same nominal

distance from the axis about which the disk rotates. (2) The tracks of a disk storage device that can be accessed without repositioning the access mechanism.

daisy-chained cable. A type of cable that has two or more connectors attached in series.

data. (1) A representation of facts, concepts, or instructions in a formalized manner suitable for communication, interpretation, or processing by humans or automatic means. (2) Any representations, such as characters or analog quantities, to which meaning is, or might be assigned.

decibel (dB). (1) A unit that expresses the ratio of two power levels on a logarithmic scale. (2) A unit for measuring relative power. The number of decibels is ten times the logarithm (base 10) of the ratio of the measured power levels; if the measured levels are voltages (across the same or equal resistance), the number of decibels is 20 times the log of the ratio.

decoupling capacitor. A capacitor that provides a

low-impedance path to ground to prevent common coupling between states of a circuit.

Deutsche Industrie Norm (DIN). (1) German Industrial Norm. (2) The committee that sets German dimension standards.

digit. (1) A graphic character that represents an integer, for example, one of the characters 0 to 9. (2) A symbol that represents one of the non-negative integers smaller than the radix. For example, in decimal notation, a digit is one of the characters from 0 to 9.

digital. (1) Pertaining to data in the form of digits. (2) Contrast with analog.

DIN. Deutsche Industrie Norm.

DIN Connector. One of the connectors specified by the DIN standardization committee.

DIP. Dual in-line package.

direct memory access
(DMA). A method of
transferring data between main
storage and I/O devices that
does not require processor
intervention.

disk. Loosely, a magnetic disk unit.

diskette. A thin, flexible magnetic disk and a semi-rigid protective jacket, in which the disk is permanently enclosed. Synonymous with flexible disk.

DMA. Direct memory access.

DSR. Data set ready. Associated with modem control.

DTR. Data terminal ready. Associated with modem control.

dual in-line package (DIP). A widely used container for an integrated circuit. DIPs are pins usually in two parallel rows. These pins are spaced 1/10 inch apart and come in different configurations ranging from 14-pin to 40-pin configurations.

EBCDIC. Extended binary-coded decimal interchange code.

ECC. Error checking and correction.

edge connector. A terminal block with a number of contacts attached to the edge of a printed circuit board to facilitate plugging into a foundation circuit.

EIA. Electronic Industries Association.

EIA/CCITT. Electronic Industries Association/Consultative Committee on International Telegraphy and Telephone.

end-of-text character (ETX). A transmission control character used to terminate text.

end-of-transmission character (EOT). A transmission control character used to indicate the conclusion of a transmission, which may have included one or more texts and any assoceated message headings.

EOT. end-of-transmission character.

EPROM. Erasable programmable read-only memory

erasable programmable
read-only. memory (EPROM)
A storage device whose
contents can be erased by
ultraviolet means and new
contents stored by electrical
means. EPROM information is
not destroyed when power is
removed.

error checking and correction (ECC). The detection and correction of all single-bit, double-bit, and some multiple-bit errors.

ETX. End-of-text character.

extended binary-coded decimal interchange code. (EBCDIC) A set of 256 characters, each represented by eight bits.

flexible disk. Synonym for diskette.

firmware. Memory chips with integrated programs already incorporated on the chip.

gate. (1) A device or circuit that has no output until it is triggered into operation by one or more enable signals, or until an input signal exceeds a predetermined threshold amplitude. (2) A signal that triggers the passage of other signals through a circuit.

graphic. A symbol produced by a process such as handwriting, drawing, or printing.

hertz (Hz). A unit of frequency equal to one cycle per second.

hex. Abbreviation for hexadecimal.

hexadecimal (Hex). Pertaining to a selection, choice, or condition that has 16 possible values or states. These values or states usually contain 10 digits and 6 letters, A through F/ Hexadecimal digits are equivalent to a power of 16.

high-order position. The leftmost position in a string of characters.

Hz. Hertz.

interface. A device that alters or converts actual electrical signals between distinct devices, programs, or systems.

k. An abbreviation for the prefix kilo; that is, 1,000 decimal notation.

K. When referring to storage capacity, 2 to the tenth power; 1,024 in decimal notation.

KB (Kilobyte). 1,024 bytes.

k byte. 1,024 bytes.

kHz. A unit of frequency equal to 1,000 hertz.

kilo(k). One thousand.

latch. (1) A feedback loop in symmetrical digital circuits used to maintain a state. (2) A simple logic-circuit storage element comprising two gates as a unit.

LED. Light-emitting diode.

light-emitting diode (LED). A semi-conductor chip that gives off visible or infrared light when activated.

low-order position. The rightmost position in a string of characters.

m. (1) Milli; one thousand or thousandth part. (2) Meter.

M (Mega). 1,000,000 in decimal notation. When referring to storage capacity, 2 to the twentieth power; 1,048,576 in decimal notation.

mA. Milliampere.

machine language. (1) A language that is used directly by a machine. (2) Another term for computer instruction code.

main storage. A storage device in which the access time is effectively independent of the location of the data.

MB. Megabyte, 1,048,576 bytes.

mega (M). 10 to the sixth power, 1,000,000 in decimal notation. When referring to storage capacity, 2 to the twentieth power. 1,048,576 in decimal notation.

megabyte (MB). 1,048,576 bytes.

megahertz (MHz). A unit of measure of frequency. One megahertz equals 1,000,000 hertz.

MFM. Modified frequency modulation.

MHz. Megahertz.

microprocessor. An integrated circuit that accepts coded instructions for execution; the instructions may be entered, integrated, or stored internally.

microsecond. (µs) One-millionth of a second.

milli(m). One thousand or one thousandth.

milliampere(mA). One thousandth of an ampere.

millisecond(ms). One thousandth of a second.

mnemonic. A symbol chosen to assist the human memory; for example, an abbreviation such as "mpy" for "multiply."

mode. (1) A method of operation; for example, the binary mode, the interpretive mode, the alphanumeric mode. (2) The most frequent value in the statistical sense.

modem

(Modulator-Demodulator). A device that converts serial (bit by bit) digital signals from a business machine (or data terminal equipment) to analog signals which are suitable for transmission in a telephone network. The inverse function is also performed by the modem on reception of analog signals.

modified frequency modulation (MFM). The process of varying the amplitude and frequency of the "write" signal. MFM pertains to the number of bytes of storage that can be stored on the recording media. The number of bytes is twice the number contained in the same unit area of recording media at single density.

modulo check. A calculation performed on values entered into a system. This calculation is designed to detect errors.

monitor. (1) A device that observes and verifies the operation of a data processing system and indicates any specific departure from the norm. (2) A television type display, such as the IBM Monochrome Display. (3) Software or hardware that observes, supervises, controls, or verifies the operations of a

ms. Millisecond; one thousandth of a second.

system.

multiplexer. A device capable of distributing the events of an interleaved sequence to the respective activities.

NAND. A logic operator having the property that if P is a statement, Q is a statement, R is a statement, ..., then the NAND of P,Q,R,...is true if at least one statement is false, false if all statements are true.

nanosecond. (ns) One-billionth of a second.

nonconjunction. (1) The dyadic Boolean operation the result of which has the Boolean value 0 if, and only if, each operand has the Boolean value 1.

non-return-to-zero inverted (NRZI). A transmission encoding method in which the data terminal equipment changes the signal to the opposite state to send a binary 0 and leaves it in the same state to send a binary 1.

NOR. A logic operator having the property that if P is a statement, Q is a statement, R is a statement, ...,then the NOR of P,Q,R,...is true if all statements are false, false if at least one statement is true.

NOT. A logical operator having the property that if P is a statement, then the NOT of P is true if P is false, false if P is true.

NRZI. Non-return-to-zero inverted.

ns. Nanosecond; one-billionth of a second.

operating system. Software that controls the execution of programs; an operating system may provide services such as resource allocation, scheduling, input/output control, and data management.

OR. (1) A logic operator having the property that if P is a statement, Q is a statement, R is a statement, ..., then the OR of P,Q,R,... is true if at least one statement is true, false if all statements are false.

output. Pertaining to a device, process, or channel involved in an output process, or to the data or states involved in an output process.

output process. (1) The process that consists of the delivery of data from a data processing system, or from any part of it. (2) The return of information from a data processing system to an end user, including the translation of data from a machine language to a language that the end user can understand.

overcurrent. A current of higher than specified strength.

overvoltage. A voltage of higher than specified value.

parallel. (1) Pertaining to the concurrent or simultaneous operation of two or more devices, or to the concurrent performance of two or more activities. (2) Pertaining to the concurrent or simultaneous occurrence of two or more related activities in multiple devices or channels.

(3) Pertaining to the simultaneity of two or more processes. (4) Pertaining to the simultaneous processing of the individual parts of a whole, such as the bits of a character and the characters of a word, using separate facilities for the various parts. (5) Contrast with serial.

PEL. Picture element.

personal computer. A small home or business computer that has a processor and keyboard and that can be connected to a television or some other monitor. An optional printer is usually available.

picture element (PEL). (1) The smallest displayable unit on a display. (2) Synonymous with pixel, PEL.

pinout. A diagram of functioning pins on a pinboard.

pixel. Picture element.

polling. (1) Interrogation of devices for purposes such as to avoid contention, to determine operational status, or to determine readiness to send or receive data. (2) The process whereby stations are invited, one at a time, to transmit.

port. An access point for data entry or exit.

printed circuit board. A piece of material, usually fiberglass, that contains a layer of conductive material, usually metal. Miniature electronic components on the fiberglass transmit electronic signals through the board by way of the metal layers.

program. (1) A series of actions designed to achieve a certain result. (2) A series of instructions telling the computer how to handle a

problem or task. (3) To design, write, and test computer programs.

programable read-only memory (PROM). Non-erasable programable memory. PROM information is not destroyed when power is removed.

programming language. (1) An artificial language established for expressing computer programs. (2) A set of characters and rules, with meanings assigned prior to their use, for writing computer programs.

PROM. Programmable read-only memory.

propagation delay. The time necessary for a signal to travel from one point on a circuit to another.

radix. (1) In a radix numeration system, the positive integer by which the weight of the digit place is multiplied to obtain the weight of the digit place with the next higher weight; for example, in the decimal

numeration system, the radix of each digit place is 1.0.

(2) Another term for base.

radix numeration system. A positional representation system in which the ratio of the weight of any one digit place to the weight of the digit place with the next lower weight is a positive integer. The permissible values of the character in any digit place range from zero to one less than the radix of the digit place.

RAS. Row address strobe.

RGBI. Red-green-blue-intensity.

read-only memory (ROM). A storage device whose contents cannot be modified, except by a particular user, or when operating under particular conditions; for example, a storage device in which writing is prevented by a lockout.

read/write memory. A storage device whose contents can be modified.

red-green-blue-intensity (RGBI). The description of a direct-drive

color monitor which accepts red, green, blue, and intensity signal inputs.

register. (1) A storage device, having a specified storage capacity such as a bit, a byte, or a computer word, and usually intended for a special purpose. (2) On a calculator, a storage device in which specific data is stored.

RF modulator. The device used to convert the composite video signal to the antenna level input of a home TV.

ROM. Read-only memory.

ROM/BIOS. The basic input/output system resident in ROM, which provides the device level control of the major I/O devices in the computer system.

row address strobe (RAS). A signal that latches the row addresses in a memory chip.

RS-232C. The standards set by the EIA for communications between computers and external equipment. RTS. Request to send. Associated with modem control.

run. A single continuous performance of a computer program or routine.

scan line. The use of a cathode beam to test the cathode ray tube of a display used with a personal computer.

schematic. The description, usually in diagram form, of the logical and physical structure of an entire data base according to a conceptual model.

sector. That part of a track or band on a magnetic drum, a magnetic disk, or a disk pack that can be accessed by the magnetic heads in the course of a predetermined rotational displacement of the particular device.

serdes. Serializer/deserializer.

serial. (1) Pertaining to the sequential performance of two or more activities in a single device. In English, the modifiers serial and parallel usually refer to devices, as opposed to sequential and

consecutive, which refer to processes. (2) Pertaining to the sequential or consecutive occurrence of two or more related activities in a single device or channel.

(3) Pertaining to the sequential processing of the individual parts of a whole, such as the bits of a character or the characters of a word, using the same facilities for successive parts. (4) Contrast with parallel.

sink. A device or circuit into which current drains.

software. (1) Computer programs, procedures, rules, and possible associated documentation concerned with the operation of a data processing system. (2) Contrasta with hardware.

source. The origin of a signal or electrical energy.

source circuit. (1) Generator circuit. (2) Control with sink.

SS. Start-stop transmission.

start bit. Synonym for start signal.

start-of-text character (STX). A transmission control character that precedes a test and may be used to terminate the message heading.

start signal. (1) A signal to a receiving mechanism to get ready to receive data or perform a function. (2)In a start-stop system, a signal preceding a character or block that prepares the receiving device for the reception of the code elements. Synonymous with start bit.

start-stop (SS)

transmission. (1) A synchronous transmission such that a group of signals representing a character is preceded by a start signal and followed by a stop signal. (2) Asynchronous transmission in which a group of bits is preceded by a start bit that prepares the receiving mechanism for the reception and registration of a character and is followed by at least one stop bit that enables the receiving mechanism for the reception and registration of a character and is followed by at least one stop bit that enables the receiving mechanism to come to an idle condition pending the reception of the next character.

stop bit. Synonym for stop signal.

stop signal. (1) A signal to a receiving mechanism to wait for the next signal. (2)In a start-stop system, a signal following a character or block that prepares the receiving device for the reception of a subsequent character or block. Synonymous with stop bit.

strobe. (1) An instrument used to determine the exact speed of circular or cyclic movement. (2) A flashing signal displaying an exact event.

STX. Start-of-text character.

synchronous transmission. Data transmission in which the sending and receiving devices are operating continuously at the same frequency and are maintained, by means of correction, in a desired phase relationship.

text. In ASCII and data communication, a sequence of characters treated as an entity if preceded and terminated by one STX and one ETX transmission control, respectively.

track. The path or one of the set of paths, parallel to the reference edge on a data medium, associated with a single reading or writing component as the data medium moves past the component. (2) The portion of a moving data medium such as a drum, tape, or disk, that is accessible to a given reading head position.

transistor-transistor logic (TTL). A circuit in which the multiple-diode cluster of the diode-transistor logic circuit has been replaced by a multiple-emitter transistor.

TTL. Transistor-transistor logic.

TX Data. Transmit data.

Associated with modem control. External connections of the RS-232C asynchronous communications adapter interface.

video. Computer data or displayed on a cathode ray tube monitor or display. write precompensation. The varying of the timing of the head current from the outer

tracks to the inner tracks of the diskette to keep a constant write signal.
